PREAMBLE

Since 1980, the American College of Cardiology (ACC) and American Heart Association (AHA) have translated scientific evidence into clinical practice guidelines (guidelines) with recommendations to improve cardiovascular health. These guidelines, which are based on systematic methods to evaluate and classify evidence, provide a cornerstone for quality cardiovascular care. The ACC and AHA sponsor the development and publication of guidelines without commercial support, and members of each organization volunteer their time to the writing and review efforts. Guidelines are official policy of the ACC and AHA.

Intended Use

Practice guidelines provide recommendations applicable to patients with or at risk of developing cardiovascular disease. The focus is on medical practice in the United States, but guidelines developed in collaboration with other organizations may have a global impact. Although guidelines may be used to inform regulatory or payer decisions, their intent is to improve patients’ quality of care and align with patients’ interests. Guidelines are intended to define practices meeting the needs of patients in most, but not all, circumstances and should not replace clinical judgment.

Clinical Implementation

Guideline recommended management is effective only when followed by healthcare providers and patients. Adherence to recommendations can be enhanced by shared decision making between healthcare providers and patients, with patient engagement in selecting interventions based on individual values, preferences, and associated conditions and comorbidities.

Methodology and Modernization

The ACC/AHA Task Force on Clinical Practice Guidelines (Task Force) continuously reviews, updates, and modifies guideline methodology on the basis of published standards from organizations including the Institute of Medicine1,2 and on the basis of internal reevaluation. Similarly, the presentation and delivery of guidelines are reevaluated and modified on the basis of evolving technologies and other factors to facilitate optimal dissemination of information at the point of care to healthcare professionals. Given time constraints of busy healthcare providers and the need to limit text, the current guideline format delineates that each recommendation be supported by limited text (ideally, <250 words) and hyperlinks to supportive evidence summary tables. Ongoing efforts to further limit text are underway. Recognizing the importance of cost-value considerations in certain guidelines, when appropriate and feasible, an analysis of the value of a drug, device, or intervention may be performed in accordance with the ACC/AHA methodology.3

To ensure that guideline recommendations remain current, new data are reviewed on an ongoing basis, with full guideline revisions commissioned in approximately 6-year cycles. Publication of new, potentially practice-changing study results that are relevant to an existing or new drug, device, or management strategy will prompt evaluation by the Task Force, in consultation with the relevant guideline writing committee, to determine whether a focused update should be commissioned. For additional information and policies regarding guideline development, we encourage readers to...
Selection of Writing Committee Members

The Task Force strives to avoid bias by selecting experts from a broad array of backgrounds. Writing committee members represent different geographic regions, sexes, ethnicities, races, intellectual perspectives/biases, and scopes of clinical practice. The Task Force may also invite organizations and professional societies with related interests and expertise to participate as partners, collaborators, or endorsers.

Relationships With Industry and Other Entities

The ACC and AHA have rigorous policies and methods to ensure that guidelines are developed without bias or improper influence. The complete relationships with industry and other entities (RWI) policy can be found online. Appendix 1 of the current document lists writing committee members’ relevant RWI. For the purposes of full transparency, writing committee members’ comprehensive disclosure information is available online. Comprehensive disclosure information for the Task Force is also available online.

Evidence Review and Evidence Review Committees

When developing recommendations, the writing committee uses evidence-based methodologies that are based on all available data.\(^4\)\(^-\)\(^6\) Literature searches focus on randomized controlled trials (RCTs) but also include registries, nonrandomized comparative and descriptive studies, case series, cohort studies, systematic reviews, and expert opinion. Only key references are cited.

An independent evidence review committee (ERC) is commissioned when there are 1 or more questions deemed of utmost clinical importance that merit formal systematic review. This systematic review will strive to determine which patients are most likely to benefit from a drug, device, or treatment strategy and to what degree. Criteria for commissioning an ERC and formal systematic review include: a) the absence of a current authoritative systematic review, b) the feasibility of defining the benefit and risk in a time frame consistent with the writing of a guideline, c) the relevance to a substantial number of patients, and d) the likelihood that the findings can be translated into actionable recommendations. ERC members may include methodologists, epidemiologists, healthcare providers, and biostatisticians. When a formal systematic review has been commissioned, the recommendations developed by the writing committee on the basis of the systematic review are marked with “SR”.

Guideline-Directed Management and Therapy

The term guideline-directed management and therapy (GDMT) encompasses clinical evaluation, diagnostic testing, and pharmacological and procedural treatments. For these and all recommended drug treatment regimens, the reader should confirm the dosage by reviewing product insert material and evaluate the treatment regimen for contraindications and interactions. The recommendations are limited to drugs, devices, and treatments approved for clinical use in the United States.

Class of Recommendation and Level of Evidence

The Class of Recommendation (COR) indicates the strength of the recommendation, encompassing the estimated magnitude and certainty of benefit in proportion to risk. The Level of Evidence (LOE) rates the quality of scientific evidence that supports the intervention on the basis of the type, quantity, and consistency of data from clinical trials and other sources (Table 1).\(^4\)\(^-\)\(^6\)

Glenn N. Levine, MD, FACC, FAHA
Chair, ACC/AHA Task Force on Clinical Practice Guidelines

1. INTRODUCTION

The purpose of this focused update is to update the “2013 ACCF/AHA Guideline for the Management of Heart Failure”\(^9\) (2013 HF guideline) in areas in which new evidence has emerged since its publication. For this update and future heart failure (HF) guidelines, the Heart Failure Society of America (HFSA) has partnered with the ACC and AHA to provide coordinated guidance on the management of HF.

The scope of the focused update includes revision to the sections on biomarkers; new therapies indicated for stage C HF with reduced ejection fraction (HFrEF); updates on HF with preserved ejection fraction (HFpEF); new data on important comorbidities, including sleep apnea, anemia, and hypertension; and new insights into the prevention of HF.

This focused update represents the second part of a 2-stage publication; with the first part having been published as the “2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure,”\(^10\) which introduced guidance on new therapies, specifically for the use of an angiotensin receptor–neprilysin inhibitor (ARNI) (valsartan/sacubitril) and a sinoatrial node modulator (ivabradine). That focused update was published concurrently with the European Society of Cardiology’s complete guideline, “2016 ESC Guidelines
for the Diagnosis and Treatment of Acute and Chronic Heart Failure.”

1.1. Methodology and Evidence Review
To identify key data that influence guideline recommendations, the Task Force and members of the 2013 HF guideline writing committee reviewed clinical trials that were presented at the annual scientific meetings of the ACC, AHA, and European Society of Cardiology and other scientific meetings and that were published in peer-reviewed format from April 2013 through November 2016. The evidence is summarized in tables in the Online Data Supplement. All recommendations (new, modified, and unchanged) for each clinical section are included to provide a comprehensive assessment. The text explains new and modified recommendations, whereas recommendations from the previous guideline
that have been deleted or superseded no longer appear. Please consult the full-text version of the 2013 HF guideline8 for text and evidence tables supporting the unchanged recommendations and for clinical areas not addressed in this focused update. Individual recommendations in this focused update will be incorporated into the full-text guideline in the future. Recommendations from the prior guideline that remain current have been included for completeness, but the LOE reflects the COR/LOE system used when the recommendations were initially developed. New and modified recommendations in this focused update reflect the latest COR/LOE system, in which LOE B and C are subcategorized for greater specificity.4–6 The section numbers correspond to the full-text guideline sections.

1.2. Organization of the Writing Group

For this focused update, representative members of the 2013 HF guideline writing committee were invited to participate. They were joined by additional invited members to form a new writing group, which is referred to as the 2017 HF focused update writing group. Members were required to disclose all RWI relevant to the data under consideration. The group was composed of experts representing general cardiologists, HF and transplantation specialists, electrophysiologists, pharmacists, and general internists. The 2017 HF focused update writing group included representatives from the ACC, AHA, and HFSA, as well as the American Academy of Family Physicians, American College of Chest Physicians, American College of Physicians, and International Society for Heart and Lung Transplantation.

1.3. Document Review and Approval

The focused update was reviewed by 2 official reviewers each nominated by the ACC, AHA, and HFSA; 1 reviewer each from the American Academy of Family Physicians, American College of Chest Physicians, and International Society for Heart and Lung Transplantation; and 19 individual content reviewers. Reviewers’ RWI information is published in this document (Appendix 2).

This document was approved for publication by the governing bodies of the ACC, AHA, and HFSA.

6. INITIAL AND SERIAL EVALUATION OF THE HF PATIENT

6.3. Biomarkers

Assays for BNP (B-type natriuretic peptide) and NT-proBNP (N-terminal pro-B-type natriuretic peptide), which are both natriuretic peptide biomarkers, have been used increasingly to establish the presence and severity of HF. In general, both natriuretic peptide biomarker values track similarly, and either can be used in patient care settings as long as their respective absolute values and cutpoints are not used interchangeably. Notably, BNP, but not NT-proBNP, is a substrate for neprilysin. Therefore, ARNI increases BNP levels12 but not NT-proBNP levels.13 Note that the type of natriuretic peptide assay that has been performed must be considered during interpretation of natriuretic peptide biomarker levels in patients on ARNI. In 2 studies with ARNI, NT-proBNP levels were reduced,12,14 with the reduction in 1 study being associated with improved clinical outcomes.12

A substantial evidence base exists that supports the use of natriuretic peptide biomarkers to assist in the diagnosis or exclusion of HF as a cause of symptoms (eg, dyspnea, weight gain) in the setting of chronic ambulatory HF15–21 or in the setting of acute care with decompensated HF,22–30 especially when the cause of dyspnea is unclear. The role of natriuretic peptide biomarkers in population screening to detect incident HF is emerging.31–37 Elevated plasma levels of natriuretic peptide biomarkers are associated with a wide variety of cardiac and noncardiac causes (Table 2).38–42 Obesity may be associated with lower natriuretic peptide concentrations, and this may modestly reduce diagnostic sensitivity in morbidly obese patients.42

Table 2. Selected Potential Causes of Elevated Natriuretic Peptide Levels38–41

<td>For patients at risk of developing HF, natriuretic peptide biomarker–based screening followed by team-based care, including a cardiovascular specialist optimizing GDMT, can be useful to prevent the development of left ventricular dysfunction (systolic or diastolic) or new-onset HF.</td>
<td>NEW: New data suggest that natriuretic peptide biomarker screening and early intervention may prevent HF.</td>
</tr>
</tbody>
</table>

In a large-scale unblinded single-center study (STOP-HF [The St Vincent’s Screening to Prevent Heart Failure]), 85 patients at risk of HF (identified by the presence of hypertension, diabetes mellitus, or known vascular disease [eg, stage A HF]), but without established left ventricular systolic dysfunction or symptomatic HF at baseline, were randomly assigned to receive screening with BNP testing or usual primary care. Intervention-group participants with BNP levels of ≥50 pg/mL underwent echocardiography and were referred to a cardiovascular specialist who decided on further investigation and management. All patients received further coaching by a specialist nurse who emphasized individual risk and the importance of adherence to medication and healthy lifestyle behaviors. BNP-based screening reduced the composite endpoint of asymptomatic left ventricular dysfunction (systolic or diastolic) with or without newly diagnosed HF. Similarly, in another small, single-center RCT, accelerated up-titration of renin-angiotensin-aldosterone system antagonists and beta blockers reduced cardiac events in patients with diabetes mellitus and elevated NT-proBNP levels but without cardiac disease at baseline. Developing a standardized strategy to screen and intervene in patients at risk of HF can be difficult because of different definitions of HF risk, heterogeneity of prevalence in different populations, variable duration until clinical HF or left ventricular dysfunction develops, and variable interventions for risk factor modification or treatment. Further studies are needed to determine cost-effectiveness and risk of such screening, as well as its impact on quality of life (QoL) and mortality rate.

</tr>
</tbody>
</table>

Natriuretic peptide biomarker testing in the setting of chronic ambulatory HF provides incremental diagnostic value to clinical judgment, especially when the etiology of dyspnea is unclear. In emergency settings, natriuretic peptide biomarker levels usually have higher sensitivity than specificity and may be more useful for ruling out than ruling in HF. Although lower values of natriuretic peptide biomarkers exclude the presence of HF, and higher values have reasonably high positive predictive value to diagnose HF, clinicians should be aware that elevated plasma levels for both natriuretic peptides have been associated with a wide variety of cardiac and noncardiac causes (Table 2).

6.3.3 Biomarkers for Prognosis or Added Risk Stratification: Recommendations

**Biomarkers: Recommendations for Prognosis**

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>I</td>
<td>A</td>
<td>Measurement of BNP or NT-proBNP is useful for establishing prognosis or disease severity in chronic HF.</td>
<td>2013 recommendation remains current.</td>
</tr>
</tbody>
</table>
Higher levels of natriuretic peptide biomarkers on admission are usually associated with greater risk for clinical outcomes, including all-cause and cardiovascular mortality, morbidity, and composite outcomes, across different time intervals in patients with decompensated HF, often without obvious myocardial ischemia or underlying coronary artery disease (CAD), and this is associated with worse clinical outcomes and higher risk of death.27,93–100 Studies have demonstrated incremental prognostic value of these biomarkers to standard approaches of cardiovascular disease risk assessment.27,95 However, there were differences in the risk prediction models, assay cutpoints, and lengths of follow-up.27 Furthermore, not all patients may need biomarker measurement for prognostication, especially if they already have advanced HF with established poor prognosis or persistently elevated levels of biomarkers in former settings. Therefore, assays of natriuretic peptide biomarkers for incremental prognostication should not preclude good clinical judgment; an individualized approach to each patient is paramount.

**IIa** B-NR During a HF hospitalization, a predischarge natriuretic peptide level can be useful to establish a postdischarge prognosis.93,96,104–113

**NEW:** Current recommendation reflects new observational studies. See Online Data Supplements A and B.

Predischarge natriuretic peptide biomarker levels and the relative change in levels during hospital treatment are strong predictors of the risk of death or hospital readmission for HF.93,96,104–113 Several studies have suggested that predischarge natriuretic peptide biomarker levels had higher reclassification and discrimination value than clinical variables in predicting outcomes.93,101,105–111 Patients with higher predischarge levels and patients who do not have a decrease in natriuretic peptide biomarker levels during hospitalization have worse outcomes.93,104,106–111 Although observational or retrospective studies have suggested that patients with natriuretic peptide biomarker reduction had better outcomes than those without any changes or with a biomarker rise,93,101,112,113 targeting a certain threshold, value, or relative change in these biomarker levels during hospitalization may not be practical or safe for every patient and has not been tested in a prospective large-scale trial. Clinical assessment and adherence to GDMT should be the emphasis, and the prognostic value of a predischarge value or relative changes does not imply the necessity for serial and repeated biomarker measurements during hospitalization.

**IIb** B-NR In patients with chronic HF, measurement of other clinically available tests, such as biomarkers of myocardial injury or fibrosis, may be considered for additive risk stratification.27,93,96,98,99,103,114–119

**MODIFIED:** 2013 recommendations have been combined into prognosis section, resulting in LOE change from A to B-NR. See Online Data Supplements A and B.

Biomarkers of myocardial fibrosis (eg, soluble ST2 receptor, galectin-3, high-sensitivity cardiac troponin, and others) are predictive of hospitalization and death in patients with HF and also are additive to natriuretic peptide biomarker levels in their prognostic value.117,119–126 A combination of biomarkers may ultimately prove to be more informative than single biomarkers.127

**Figure 1. Biomarkers Indications for Use.**

| | | Angiotensin-converting enzyme (ACE) inhibitors reduce morbidity and mortality in heart failure with reduced ejection fraction (HFREF). Randomized controlled trials (RCTs) clearly establish the benefits of ACE inhibition in patients with mild, moderate, or severe symptoms of HF and in patients with or without coronary artery disease.128-133 ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough but also may contribute to their beneficial effect through vasodilation.

Angiotensin receptor blockers (ARBs) were developed with the rationale that angiotensin II production continues in the presence of ACE inhibition, driven through alternative enzyme pathways. ARBs do not inhibit kininase and are associated with a much lower incidence of cough and angioedema than ACE inhibitors; but like ACE inhibitors, ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium. Long-term therapy with ARBs produces hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system and have been shown in RCTs131-134 to reduce morbidity and mortality, especially in ACE inhibitor-intolerant patients.

In ARNI, an ARB is combined with an inhibitor of nephrilysin, an enzyme that degrades natriuretic peptides, bradykinin, adrenomedullin, and other vasoactive peptides. In an RCT that compared the first approved ARNI, valsartan/sacubitril, with enalapril in symptomatic patients with HFREF tolerating an adequate dose of either ACE inhibitor or ARB, the ARNI reduced the composite endpoint of cardiovascular death or HF hospitalization significantly, by 20%.138 The benefit was seen to a similar extent for both death and HF hospitalization and was consistent across subgroups. The use of ARNI is associated with the risk of hypotension and renal insufficiency and may lead to angioedema, as well. | |
| I | ACE-I: A | The use of ACE inhibitors is beneficial for patients with prior or current symptoms of chronic HFREF to reduce morbidity and mortality.128-133,134 | 2013 recommendation repeated for clarity in this section. |
| See Online Data Supplement 18. | | | |
| | | ACE inhibitors have been shown in large RCTs to reduce morbidity and mortality in patients with HFREF with mild, moderate, or severe symptoms of HF, with or without coronary artery disease.128-133 Data suggest that there are no differences among available ACE inhibitors in their effects on symptoms or survival.131 ACE inhibitors should be started at low doses and titrated upward to doses shown to reduce the risk of cardiovascular events in clinical trials. ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium (>5.0 mEq/L).

Angioedema occurs in <1% of patients who take an ACE inhibitor, but it occurs more frequently in blacks and women.144 Patients should not be given ACE inhibitors if they are pregnant or plan to become pregnant. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough in up to 20% of patients but also may contribute to their beneficial vasodilation.

 Patients intolerant to ACE inhibitors because of cough or angioedema should be started on ARBs; patients already tolerating ACE inhibitors in their effects on symptoms or survival.131 ACE inhibitors should be started at low doses and titrated upward, with an attempt to use doses shown to reduce the risk of cardiovascular events in clinical trials. ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium (>5.0 mEq/L). Although ARBs are alternatives for patients with ACE inhibitor–induced angioedema, caution is advised because some patients have also developed angioedema with ARBs. Head-to-head comparisons of an ARB versus ARNI for HF do not exist. For those patients for whom an ACE inhibitor or ARNI is inappropriate, use of an ARB remains advised. | 2013 recommendation repeated for clarity in this section. |
| I | ARB: A | The use of ARBs to reduce morbidity and mortality is recommended in patients with prior or current symptoms of chronic HFREF who are intolerant to ACE inhibitors because of cough or angioedema,134-137,145,146 | |

<tbody>
<tr>
<td>I</td>
<td>ARNI: B-R</td>
<td>In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality.<strong>NEW:</strong> New clinical trial data necessitated this recommendation.</td>
<td></td>
</tr>
</tbody>
</table>

Benefits of ACE inhibitors with regard to decreasing HF progression, hospitalizations, and mortality rate have been shown consistently for patients across the clinical spectrum, from asymptomatic to severely symptomatic HF. Similar benefits have been shown for ARBs in populations with mild-to-moderate HF who are unable to tolerate ACE inhibitors. In patients with mild-to-moderate HF (characterized by either 1) mildly elevated natriuretic peptide levels, BNP [B-type natriuretic peptide] >150 pg/mL or NT-proBNP [N-terminal pro-B-type natriuretic peptide] >600 pg/mL; or 2) BNP ≥100 pg/mL or NT-proBNP ≥400 pg/mL with a prior hospitalization in the preceding 12 months) who were able to tolerate both a target dose of enalapril (10 mg twice daily) and then subsequently an ARNI (valsartan/sacubitril; 200 mg twice daily, with the ARB component equivalent to valsartan 160 mg), hospitalizations and mortality were significantly decreased with the valsartan/sacubitril compound compared with enalapril. The target dose of the ACE inhibitor was consistent with that known to improve outcomes in previous landmark clinical trials.**125** This ARNI has been approved for patients with symptomatic HFrEF and is intended to be substituted for ACE inhibitors or ARBs. HF effects and potential off-target effects may be complex with inhibition of the nephrilysin enzyme, which has multiple biological targets. Use of an ARNI is associated with hypotension and a low-frequency incidence of angioedema. To facilitate initiation and titration, the approved ARNI is available in 3 doses that include a dose that was not tested in the HF trial; the target dose used in the trial was 97/103 mg twice daily.**126** Clinical experience will provide further information about the optimal titration and tolerability of ARNI, particularly with regard to blood pressure, adjustment of concomitant HF medications, and the rare complication of angioedema.**126**

**NEW:** Available evidence demonstrates a potential signal of harm for a concomitant use of ACE inhibitors and ARNI.

**III: Harm**

| B-R | ARNI should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor.**144,145** | **NEW:** |

Oral nephrilysin inhibitors, used in combination with ACE inhibitors can lead to angioedema and concomitant use is contraindicated and should be avoided. A medication that represented both a nephrilysin inhibitor and an ACE inhibitor, omapatrilat, was studied in both hypertension and HF, but its development was terminated because of an unacceptable incidence of angioedema**144,145** and associated significant morbidity. This adverse effect was thought to occur because both ACE and nephrilysin break down bradykinin, which directly or indirectly can cause angioedema.**144,150** An ARNI should not be administered within 36 hours of switching from or to an ACE inhibitor.

**NEW:** New clinical trial data.

**NEW:**

| C-EO | ARNI should not be administered to patients with a history of angioedema. | |

Omapatrilat, a nephrilysin inhibitor (as well as an ACE inhibitor and aminopeptidase P inhibitor), was associated with a higher frequency of angioedema than that seen with enalapril in an RCT of patients with HFrEF.**145** In a very large RCT of hypertensive patients, omapatrilat was associated with a 3-fold increased risk of angioedema as compared with enalapril.**145** Blacks and smokers were particularly at risk. The high incidence of angioedema ultimately led to cessation of the clinical development of omapatrilat.**151,152** In light of these observations, angioedema was an exclusion criterion in the first large trial assessing ARNI therapy in patients with hypertension**154** and then in the large trial that demonstrated clinical benefit of ARNI therapy in HFrEF.**146** ARNI therapy should not be administered in patients with a history of angioedema because of the concern that it will increase the risk of a recurrence of angioedema.

Ivabradine is a new therapeutic agent that selectively inhibits the I current in the sinoatrial node, providing heart rate reduction. One RCT demonstrated the efficacy of ivabradine in reducing the composite endpoint of cardiovascular death or HF hospitalization.**155** The benefit of ivabradine was driven by a reduction in HF hospitalization. The study included patients with HFrEF (NYHA class II-IV, albeit with only a modest representation of NYHA class IV HF) and left ventricular ejection fraction (LVEF) ≤35%, in sinus rhythm with a resting heart rate of ≥70 beats per minute. Patients enrolled included a small number with paroxysmal atrial fibrillation (<40% of the time) but otherwise in sinus rhythm and a small number experiencing ventricular pacing but with a predominant sinus rhythm. Those with a myocardial infarction within the preceding 2 months were excluded. Patients enrolled had been hospitalized for HF in the preceding 12 months and were on stable GDEM**2** for 4 weeks before initiation of ivabradine therapy. The target of ivabradine is heart rate slowing (the presumed benefit of action), but only 25% of patients studied were on optimal doses of beta-blocker therapy.**9,134,142,155** Given the well-proven mortality benefits of beta-blocker therapy, it is important to initiate and up titrate these agents to target doses, as tolerated, before assessing the resting heart rate for consideration of ivabradine initiation.**155**

*In other parts of the document, the term “GDEM” has been used to denote guideline-directed management and therapy. In this recommendation, however, the term “GDEM” has been used to denote this same concept in order to reflect the original wording of the recommendation that initially appeared in the “2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure: An Update of the 2013 ACCF/AHA Guideline for the Management of Heart Failure.”**12**

Mechanistic studies have suggested that mineralocorticoid receptor antagonists can improve measures of diastolic function in patients with HFrEF, possibly by a similar effect on remodeling.83,168 The TOPCAT (Treatment of Preserved Cardiac Function Heart Failure With an Aldosterone Antagonist) trial166 investigated the effects of spironolactone on a combined endpoint of death, aborted heart failure, and hospitalization in patients with HFrEF. A small reduction (HR=0.89) in this composite endpoint did not reach statistical significance, although HF hospitalization was reduced (HR=0.83); known side effects of hyperkalemia and rising creatinine were seen more commonly in the treatment group.166 An unusual amount of regional variation was seen in this trial, prompting a post-hoc analysis167 that showed that rates of the primary endpoint were 4-fold lower in Russia/Georgia than in North America and South America (the Americas). Rates in the Americas were comparable to those in other HFrEF trials.168,170 The post-hoc analysis showed efficacy in the Americas (HR=0.83) but not in Russia/Georgia (HR=1.10). Moreover, a sample of the Russia/Georgia population, despite having been in the active treatment arm, had nondetectable levels of the metabolite of spironolactone. These post-hoc analyses have significant limitations, but they suggest that in appropriately selected patients with symptomatic HFrEF (with ejection fraction [EF] ≥45%), elevated BNP level or HF admission within 1 year, estimated glomerular filtration rate >30 mL/min creatinine <2.5 mg/dL, and potassium <5.0 mEq/L, particularly in those with elevated BNP levels, use of spironolactone might be considered with close monitoring of potassium and renal function. Confirmatory studies are required.

With regard to the use of mineralocorticoid receptor antagonists, creatinine should be <2.5 mg/dL in men or <2.0 mg/dL in women (or estimated glomerular filtration rate >30 mL/min) and potassium should be <5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing represents best practices at initiation and during follow-up thereafter to minimize risk of hyperkalemia and worsening renal function.

### 9. IMPORTANT COMORBIDITIES IN HF

#### 9.2. Anemia: Recommendations

<td>In patients with NYHA class II and III HF and iron deficiency (ferritin &lt;100 ng/mL or 100 to 300 ng/mL if transferrin saturation is &lt;20%), intravenous iron replacement might be reasonable to improve functional status and QoL.175,174</td>
<td>NEW: New evidence consistent with therapeutic benefit.</td>
</tr>
</tbody>
</table>

See Online Data Supplement D.

Routine baseline assessment of all patients with HF includes an evaluation for anemia in addition to other baseline laboratory measurements. Anemia is independently associated with HF disease severity, and iron deficiency appears to be uniquely associated with reduced exercise capacity. When iron deficiency is diagnosed and after full evaluation for cause, intravenous repletion of iron, especially in the setting of concomitant hepcidin deficiency in HF, may improve exercise capacity and QoL. Studies examining correction of iron deficiency in HF have demonstrated improvement in surrogate endpoints, such as QoL, NT-proBNP, and LVEF; however, controlled trials have been underpowered to detect reductions in hard clinical endpoints. The FAIR-HF (Ferric Carboxymaltose Assessment in Patients With Iron Deficiency and Chronic Heart Failure) trial175 demonstrated improvements in NYHA class and functional capacity over a short-term exposure. The CONFIRM-HF (Ferric Carboxymaltose Evaluation on Performance in Patients With Iron Deficiency in Combination with Chronic Heart Failure) trial174 included a larger cohort of patients (n=304) and demonstrated improvements in 6-minute walk test. A meta-analysis of 5 prospective controlled studies (631 patients) evaluated the effect of intravenous iron on deaths, hospitalizations, and other events in patients with HF and iron deficiency.175 Patients receiving intravenous iron experienced limited but statistically significant improvements in functional capacity and LVEF but no reduction in mortality rate. The FAIR-HF 2 trial is underway to further address the potential benefit of intravenous iron in HF associated with iron deficiency. Therefore, a strong recommendation for intravenous iron repletion must await the results of an appropriately powered trial on morbidity and mortality. There is an uncertain evidence base for oral iron repletion in the setting of anemia associated with HF.
In patients with HF and anemia, erythropoietin-stimulating agents should not be used to improve morbidity and mortality.176

**NEW:** Current recommendation reflects new evidence demonstrating absence of therapeutic benefit.

Small studies evaluating the treatment of anemia in patients with HF have suggested a trend toward improvement in functional capacity and reduction in hospitalization with the use of erythropoietin-stimulating agents,177–182 but results have varied183 and have been limited because of sample size. Although a meta-analysis of 11 RCTs (n=794) comparing erythropoietin-stimulating agents to control in patients with HF demonstrated significant improvements in 6-minute walk, exercise duration, peak VO2, NYHA functional status, EF, BNP, HF-related hospitalizations, and QoL in the STAMINA-HeFT (Study of Anemia in Heart Failure) trial,183 darbepoetin alfa was not associated with significant clinical benefits. In the largest RCT to date (n=2278), correction of anemia with darbopoetin alfa did not result in benefit and resulted in a significant increase in the risk of thromboembolic events and a nonsignificant increase in fatal and nonfatal strokes, supporting findings from other trials.176,185–188 In summary, the strongest evidence on erythropoietin-stimulating agent therapy in HF suggests lack of benefit and increased adverse events. Therefore, erythropoietin-stimulating agent therapy cannot be recommended in patients with HF and anemia.

Modified (Table 15) from the 2013 HF guideline.9

ACE indicates angiotensin-converting enzyme; ARB, angiotensin receptor blocker; ARNI, angiotensin receptor-neprilysin inhibitor; BID, twice daily; CR, controlled release; CR/XL, controlled release/extended release; HF, heart failure; HFrEF, heart failure with reduced ejection fraction; N/A, not applicable; QD, once daily; and TID, 3 times daily.
9.5. Hypertension (New Section)

9.5.1. Treating Hypertension to Reduce the Incidence of HF: Recommendation

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-R</td>
<td>In patients at increased risk, stage A HF, the optimal blood pressure in those with hypertension should be less than 130/80 mm Hg.188-193</td>
<td>NEW: Recommendation reflects new RCT data.</td>
</tr>
</tbody>
</table>

A large RCT demonstrated that in those with increased cardiovascular risk (defined as age >75 years, established vascular disease, chronic renal disease, or a Framingham Risk Score >15%), control of blood pressure to a goal systolic pressure of <120 mm Hg, as determined by blood pressure assessment as per research protocol, was associated with a significant reduction in the incidence of HF191 and an overall decrease in cardiovascular death. Blood pressure measurements as generally taken in the office setting are typically 5 to 10 mm Hg higher than research measurements; thus, the goal of <130/80 mm Hg is an approximation of the target blood pressure in conventional practice. Targeting a significant reduction in systolic blood pressure in those at increased risk for cardiovascular disease is a novel strategy to prevent HF.

9.5.2. Treating Hypertension in Stage C HFrEF: Recommendation

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-E0</td>
<td>Patients with HFrEF and hypertension should be prescribed GDMT titrated to attain systolic blood pressure less than 130 mm Hg.191</td>
<td>NEW: Recommendation has been adapted from recent clinical trial data but not specifically tested per se in a randomized trial of patients with HF.</td>
</tr>
</tbody>
</table>

Clinical trials evaluating goal blood pressure reduction and optimal blood pressure–lowering agents in the setting of HFrEF and concomitant hypertension have not been done. However, it is apparent that in those patients at higher risk, blood pressure lowering is associated with fewer adverse cardiovascular events. GDMT for HFrEF with agents known to lower blood pressure should consider a goal blood pressure reduction consistent with a threshold now associated with improved clinical outcomes but not yet proven by RCTs in a population with HF.

9.5.3. Treating Hypertension in Stage C HfP EF: Recommendation

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-LD</td>
<td>Patients with HfP EF and persistent hypertension after management of volume overload should be prescribed GDMT titrated to attain systolic blood pressure less than 130 mm Hg.</td>
<td>NEW: New target goal blood pressure based on updated interpretation of recent clinical trial data.</td>
</tr>
</tbody>
</table>

The use of nitrates in the setting of HfP EF is associated with a signal of harm and, in most situations, should be avoided. For many common antihypertensive agents, including alpha blockers, beta blockers, and calcium channel blockers, there are limited data to guide the choice of antihypertensive therapy in the setting of HfP EF. Nevertheless, RAAS inhibition with ACE inhibitors, ARB (especially mineralocorticoid receptor antagonists), and possibly ARNI would represent the preferred choice. A shared decision-making discussion with the patient influenced by physician judgment should drive the ultimate choice of antihypertensive agents.

9.6. Sleep-Disordered Breathing: Recommendations

(Moved from Section 7.3.1.4, Treatment of Sleep Disorders in the 2013 HF guideline.)

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>IIIa</td>
<td>C-LD</td>
<td>In patients with NYHA class II–IV HF and suspicion of sleep-disordered breathing or excessive daytime sleepiness, a formal sleep assessment is reasonable.202,203</td>
<td>NEW: Recommendation reflects clinical necessity to distinguish obstructive versus central sleep apnea.</td>
</tr>
</tbody>
</table>

Sleep disorders are common in patients with HF. A study of adults with chronic HF treated with evidence-based therapies found that 61% had either central or obstructive sleep apnea.203 It is clinically important to distinguish obstructive sleep apnea from central sleep apnea, given the different responses to treatment. Adaptive servo-ventilation for central sleep apnea is associated with harm.218 Continuous positive airway pressure (CPAP) for obstructive sleep apnea improves sleep quality, reduces the apnea-hypopnea index, and improves nocturnal oxygenation.202,201

| IIIb| B-R| In patients with cardiovascular disease and obstructive sleep apnea, CPAP may be reasonable to improve sleep quality and daytime sleepiness.204 | NEW: New data demonstrate the limited scope of benefit expected from CPAP for obstructive sleep apnea. |

In patients with sleep apnea, a trial evaluated the impact of CPAP with usual therapy versus usual therapy alone on subsequent cardiovascular events, including HF.205 In this RCT of >2700 patients, there was no evidence of benefit on cardiovascular events at a mean follow-up of 3.7 years for CPAP plus usual care compared with usual care alone. Improvements in sleep quality were noteworthy and represented the primary indication for initiating CPAP treatment.204 However, in patients with atrial fibrillation (AF) (a frequent comorbidity noted with HF), the use of CPAP for obstructive sleep apnea was helpful. In a trial of 10132 patients with AF and obstructive sleep apnea, patients on CPAP treatment were less likely to progress to more permanent forms of AF than were patients without CPAP.205
**Recommendations for Treatment of Sleep Disorders (Continued)**

<table>
<thead>
<tr>
<th>COR</th>

<th>Recommendations</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>III: Harm</td>
<td>B-R</td>
<td>In patients with NYHA class II–IV HFrEF and central sleep apnea, adaptive servo-ventilation causes harm.203</td>
<td>NEW: New data demonstrate a signal of harm when adaptive servo-ventilation is used for central sleep apnea.</td>
</tr>
</tbody>
</table>

See Online Data Supplement G.

Mortality rate (all cause and cardiovascular) was higher with adaptive servo-ventilation plus GDMT than with GDMT alone in a single RCT to test the addition of adaptive servo-ventilation (≥5 hours/night, 7 days/week) to GDMT in patients with HFrEF and central sleep apnea.203 A similar risk has been seen in another trial, and a third trial of adaptive servo-ventilation in central sleep apnea and HF was aborted because of ethical concerns. The weight of evidence does not support the use of adaptive servo-ventilation for central sleep apnea in HFrEF.

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACC/AHA, a person has a relevant relationship if: a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document; or c) makes a competing drug or device addressed in the document; or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.

†Significant relationship.

ACC indicates American College of Cardiology; ACCF, American College of Cardiology Foundation; AHA, American Heart Association; DCRI, Duke Clinical Research Institute; DSMB, data safety monitoring board; HFSA, Heart Failure Society of America; NHLBI, National Heart, Lung, and Blood Institute; INTERMACS, Interagency Registry for Mechanically Assisted Circulatory Support; PARENT, Pulmonary artery pressure reduction with entresto; UCLA, University of California, Los Angeles; and VA, Veterans Affairs.

</table>

This table represents the relationships of reviewers with industry and other entities that were disclosed at the time of peer review, including those not deemed to be relevant to this document. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. A relationship is considered to be modest if it is less than significant under the preceding definition. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review.

American College of Physicians did not provide a peer reviewer for this document.

*Significant relationship.
†No financial benefit.

 AAP indicates American Academy of Family Physicians; ACC, American College of Cardiology; ACCF, American College of Cardiology Foundation; AHA, American Heart Association; ASA, American Stroke Association; CHEST, American College of Chest Physicians; CIHR, Canadian Institutes of Health Research; DSMB, data safety monitoring board; FH, familial hypercholesterolemia; GWGT, Get With The Guidelines; HFSA, Heart Failure Society of America; ISHLT, International Society for Heart and Lung Transplantation; NIH, National Institutes of Health; NHLBI, National Heart, Lung, and Blood Institute; NQF, National Quality Forum; PCORI, Patient-Centered Outcomes Research Institute; SCAI, Society for Cardiac Angiography and Interventions; SLNY, State University of New York; UT, University of Texas; and VA, Veterans Affairs.

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5,000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the

person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACC/AHA, a person has a relevant relationship IF: a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.
†Significant relationship.

ACC indicates American College of Cardiology; AHA, American Heart Association; DCRI, Duke Clinical Research Institute; DSMB, data safety monitoring board; HFSA, Heart Failure Society of America; INTERMACS, Interagency Registry for Mechanically Assisted Circulatory Support; PARENT, Pulmonary Artery Pressure Reduction With Entresto; UCLA, University of California, Los Angeles; and VA, Veterans Affairs.
# 2017 Heart Failure Focused Update Data Supplement

(Section numbers correspond to the 2013 full-text guideline.)

## Table of Contents

- Data Supplement A. RCTs and Meta-analyses With Biomarkers (Section 6.3) ............................................................................................................. 3
- Data Supplement B. Nonrandomized Trials/Observational Studies/Registries for Changes in or Discharge NP Levels in ADHF – Biomarkers (Section 6.3) ................................................................................................................. 15
- Data Supplement 1. RCTs Comparing ARNI (Section 7.3.2.10) ................................................................................................................................ 27
- Data Supplement 2. RCTs Comparing RAAS Inhibition (Section 7.3.2.3) ................................................................................................................. 29
- Data Supplement 3. RCTs Comparing Pharmacological Treatment for of ARNI With ACE (Section 7.3.2.10) ................................................................. 31
- Data Supplement 4. RCTs Comparing Pharmacological Treatment for Stage C HfREF (Section 7.3.2.11) ................................................................. 33
- Data Supplement C. RCTs Comparing Pharmacologic Treatment for HFpEF: Recommendations (Section 7.3.3) ............................................... 36
- Data Supplement D. RCTs Comparing Anemia (Section 9.2) ................................................................................................................................. 41
- Data Supplement E. RCTs Comparing HTN (Section 9.5) ..................................................................................................................................... 44
- Data Supplement F. Nonrandomized Trials for Hypertension (Section 9.5) ................................................................................................................ 50
- Data Supplement G. RCTs Comparing Treatment of Sleep Disorders (CPAP makers) (Section 9.6) ........................................................................ 51

## 2013 HF Guideline Data Supplement 18. ACE Inhibitors (Section 7.3.2.2) ............................................................................................................... 62

## 2013 HF Guideline Data Supplement 19. ARBs (Section 7.3.2.3) .............................................................................................................................. 65

## 2013 HF Guideline Data Supplement 20. Beta Blockers (Section 7.3.2.4) ................................................................................................................. 66

### Aim:
To assess the effects of NP-guided treatment of chronic HF on outcomes

**Study type:**
Meta-analysis

**Size:**
14 studies, 3,004 pts

### Inclusion criteria:
Prospective RCTs with adult HF pts comparing the effects of BNP or NT-proBNP-guided therapy with clinically guided therapy

### Intervention:
BNP or NT-proBNP-guided therapy (1,503)

### Comparator:
Clinically guided therapy (1,501)

### 1<sup>st</sup> endpoints:
- All-cause mortality, HF hospitalization, all-cause hospitalization, safety (adverse events)

### Results:
- All-cause mortality was significantly reduced by NP-guided treatment [HR: 0.62 (0.45–0.86); p=0.004]
- HF hospitalizations were reduced in the NP-guided group, compared with clinically guided pts [HR: 0.80 (0.67–0.94); p=0.009] as were CV admissions [HR: 0.82 (0.67–0.99); p=0.048]
- Each of the included RCTs was relatively small and 2 trials did not

**Size**: 11 studies, 2,000 pts

**Exclusion criteria**: For 2 studies, data from the 3rd ('usual care') groups were not included.

**Intervention**: BNP or NT-proBNP-guided therapy

**Comparator**: Clinically guided therapy

**1° endpoint**: Combined endpoint of all-cause mortality and HF hospitalization

**Results**: NP-guided therapy for outpatients with HF was shown to be associated with a decreased risk of death and HF hospitalizations (OR: 0.64; 95% CI: 0.43–0.95; p=0.026)

**Limitations**: Each of the included RCTs was relatively small, Benefit was not seen in some of the studies
| Savarese et al. 2013 (9) 23472172 | **Aim:** To determine whether NP-guided (BNP or NT-proBNP) therapy, compared to clinically guided therapy, improves outcomes. | **Inclusion criteria:** All randomized trials reporting clinical endpoints (all-cause mortality and/or HF related hospitalization and/or all-cause hospitalization) with comparison of BNP or NT-proBNP guided therapy vs. a control group in chronic HF pts. | **Intervention:** • BNP-guided therapy: BNP-guided: 373 • NT-proBNP guided: 872 | **Comparator:** Clinically guided therapy. • BNP group control 357 • NT-proBNP group control 1,084. | **1° endpoints** • All-cause mortality, all-cause hospitalization, HF hospitalization. **Results:** NP-guided therapy (either BNP or NT-proBNP) significantly reduced all-cause mortality (OR: 0.738; 95% CI: 0.596–0.913; p=0.005) and HF related hospitalization (OR: 0.554; 95% CI: 0.399–0.769; p=0.000), but not all-cause hospitalization (OR: 0.803; 95% CI: 0.629–1.024; p=0.077). Separate analyses on pts ≤ or >75 y using data reported in 3 trials. | • When separately assessed, NT-proBNP-guided therapy reduced all-cause mortality (OR: 0.717; 95% CI:0.563–0.914; p=0.007) and HF hospitalization (OR: 0.531; 95% CI: 0.347–0.811; p=0.003), but not all-cause hospitalization (OR: 0.779; CI:0.414–1.465; p=0.438), whereas BNP-guided therapy did not significantly reduce all-cause mortality (OR: 0.814; CI:0.518–1.279; p=0.371), HF related hospitalization (OR: 0.599; 95% CI: 0.303–1.187; p=0.14) or all-cause hospitalization (OR: 0.726; 95% CI:0.509 – 1.035; p=0.077). Analysis from 3 trials showed the composite outcome of all-cause mortality and HF hospitalization was significantly reduced by NP-guided therapy in younger pts (<75 y) (OR: 0.449; 95% CI: 0.207–0.973; p=0.043), but not in older pts (>75 y) (OR: 0.800; 95% CI: 0.423–1.513; p=0.5). |
| Li et al. 2013 (10) 23602555 | **Aim:** To assess the effects of NP-guided treatment of chronic HF on all-cause mortality and HF hospitalization. | **Inclusion criteria:** Studies with >40 pts and involved comparison of BNP-guided vs. guideline-guided drug therapy of the pts with chronic HF in the outpatient. | **Intervention:** BNP-guided therapy. **Comparator:** Clinically guided therapy. | **1° endpoint:** • Combined end point of all-cause mortality and HF hospitalization. **Results:** Significantly decreased risk of all-cause mortality (RR: 0.83; 95% CI: 0.69–0.99; p=0.035) and HF rehospitalization was significantly decreased in the pts <70 y (RR: 0.45; 95% CI: 0.33–0.61; p=0.000; or with BL higher BNP (≥2114 pg/mL) (RR: 0.53; 95% CI: 0.39–0.72; p=0.000). In the subgroup analysis, HF rehospitalization was significantly decreased in the pts <70 y (RR: 0.45; 95% CI: 0.33–0.61; p=0.000; or with BL higher BNP (≥2114 pg/mL) (RR: 0.53; 95% CI: 0.39–0.72; p=0.000). |
### Study type:
Meta-analysis

**Size:** 11 studies, 2,414 pts

### Setting

### Intervention
BNP-guided therapy

### Comparator
Clinically guided therapy

### 1° endpoint:
- All-cause mortality

### Results:
Significant mortality advantage for biomarker-guided therapy (HR: 0.69, 95% CI: 0.55–0.86) compared to control group.

N/A

### Inclusion criteria
Prospective RCTs of pts with chronic HF randomized pts to a strategy of titrating medical therapy based on the level of a circulating biomarker compared to a parallel control group, reporting all-cause mortality.

 Felker et al. 2009 (11) 19699866

### Study type:
Meta-analysis

**Size:** 6 studies; 1,627 pts

### Setting

### Intervention:
BNP-guided therapy

### Comparator:
Clinically guided therapy

### 1° endpoint:
- All-cause mortality

### Results:
Significantly lower risk of all-cause mortality (RR: 0.76; 95% CI: 0.63–0.91; p=0.003) in the BNP-guided therapy group compared with the control group.

- In pts <75 y, all-cause mortality was significantly lower in the BNP-guided group (RR: 0.52; 95% CI: 0.33–0.82; p=0.005).
- No reduction in mortality with BNP-guided therapy in pts ≥75 y (RR: 0.94; 95% CI: 0.71–1.25; p=0.70).
- All-cause hospitalization and survival free of any hospitalization was not significantly different between groups (RR: 0.82; 95% CI: 0.64–1.05; p=0.12 and RR: 1.07; 95% CI: 0.85–1.34; p=0.58, respectively).
- Additional % pts achieving target doses of ACE-inhibitors and beta blockers 21% and 22% in the BNP group and 11.7% and 12.5% in the control group, respectively.

Porapakkham et al. 2010 (12) 20308637

### Study type:
Meta-analysis

**Size:** 8 studies; 1,726 pts

### Setting

### Intervention:
BNP-guided therapy

### Comparator:
Clinically guided therapy

### 1° endpoint:
- All-cause mortality

### Results:
Significantly lower risk of all-cause mortality (RR: 0.76; 95% CI: 0.63–0.91; p=0.003) in the BNP-guided therapy group compared with the control group.

- In pts <75 y, all-cause mortality was significantly lower in the BNP-guided group (RR: 0.52; 95% CI: 0.33–0.82; p=0.005).
- No reduction in mortality with BNP-guided therapy in pts ≥75 y (RR: 0.94; 95% CI: 0.71–1.25; p=0.70).
- All-cause hospitalization and survival free of any hospitalization was not significantly different between groups (RR: 0.82; 95% CI: 0.64–1.05; p=0.12 and RR: 1.07; 95% CI: 0.85–1.34; p=0.58, respectively).
- Additional % pts achieving target doses of ACE-inhibitors and beta blockers 21% and 22% in the BNP group and 11.7% and 12.5% in the control group, respectively.

### Study Type: RCT

**Size:** 499 pts

- 1 y, and N-terminal BNP level of ≥2 times the upper limit of normal.

**Comparator:**
- Uptitration of guideline-based treatments to reduce symptoms to NYHA class of II or less (symptom guided therapy)

- **NT-proBNP <400 pg/mL if age <75 y, NT-proBNP <800 pg/mL if 75 y**

- **BNP guidance changed therapy (higher doses of ACE inhibitors, ARB, Beta blockers and higher use of spironolactone)**

- **NT-ProBNP levels were not different between groups**

- **improved outcomes in pts 60 to 75 y of age but not in those ≥75 y of age (p<0.02 for interaction).**

- **QoL improvements were similar in both the N-terminal BNP-guided and symptom guided strategies**

### BATTLESCARRED

Laichbury et al. 2009 (16)

#### Aim:
To compare the effects of NT-proBNP-guided therapy with those of intensive clinical management and with usual care

#### Study Type: RCT (Australia hospitals)

#### Size: 364 pts

- Pts admitted to a single hospital with HF, NT-proBNP >50 pmoL/l or 400 pg/mL.(included HFpEF)

#### Intervention:
Outpatient post d/c therapy guided by NT-proBNP levels
- Target: NT-proBNP <150 pmoL/l (1,270 pg/mL)

#### Comparators:
- Therapy guided by intensive clinical management, or according to usual care

- **1° endpoints:**
  - Mortality

- **Results:**
  - 1-y mortality was less in both the hormone (9.1%) and clinically-guided (9.1%) groups compared with usual care (18.9%; p=0.03)
  - 3 y mortality was selectively reduced in pts ≤75 y receiving hormone guided treatment (15.5%) compared with either clinically managed treatment (30.9%; p=0.048) or usual care (31.3%; p=0.021).
  - NP guidance changed therapy
  - NT-ProBNP levels were not different between groups

### Berger et al. 2010 (17)

#### Aim:
To investigate whether the addition of NT-proBNP-guided, intensive pt management to multidisciplinary care improves outcome in pts following hospitalization due to HF

#### Inclusion criteria:
Pts admitted to a hospital with HF, NYHA III or IV on admission, Cardiothoracic Index>0.5 or LVEF <40%

#### Intervention:
Outpatient post discharge discontinue
- BM: NT-proBNP-guided, intensive up-titration of medication by HF specialists in high-risk pts.
  - Target: NT-proBNP (<2,200 pg/mL)

#### Comparators:
- Multidisciplinary care: 2 consultations from an HF

#### 1° endpoints:
- Hospitalization

- **Results:**
  - Pt management reduced HF hospitalization (488 D) compared with the multidisciplinary care (1254 D) and usual care (1,588 d) groups (p<0.0001)
  - Combined end point of death or HF rehospitalization was lower

- NT-ProBNP levels were not different between groups: Pt management group had the highest proportion of RAAS inhibition triple-therapy

- Death rate was similar between the pt management (22%) and multidisciplinary care groups (22%), but was lower compared with the usual care group (39%; vs. pt management: p<0.02; vs. multidisciplinary care: p<0.02)
### Study 1: PRIMA
**Aim:** To assess whether management by an individualized NT-proBNP target would lead to improved outcome compared with HF management guided by clinical assessment alone.

**Study Type:** RCT

**Size:** 345 pts

**Inclusion criteria:** Hospitalized HF pts with for decompensated, symptomatic HF with NT-proBNP levels >1,700 pg/mL at admission (included HFpEF)

**Intervention:** After discharge discontinue outpatient management guided by an individually set NT-proBNP (n=174) defined by the lowest level at discharge or 2 wk thereafter.

**Comparators:** Clinically-guided outpatient management (n=171)

**1st endpoints:** Number of d alive outside the hospital after index

**Results:** Management guided by NT-proBNP target did not significantly improve the 1st endpoint (p=0.49)

- In the NT-proBNP-guided group mortality was lower, as 46 pts died (26.5%) vs. 57 (33.3%) in the clinically guided group, but this was not statistically significant (p=0.21)
- Individualized NT-proBNP target increased the use of HF medication (p=0.006)

### Study 2: SIGNAL HF Trial
**Aim:** To investigate if NT-proBNP-guided therapy in HF pts in 1st care would improve clinical outcomes over and above treatment according to guidelines

**Study Type:** RCT

**Size:** 345 pts

**Inclusion criteria:** Ambulatory HF pts NYHA class II-IV, LVEF <50% and NT-proBNP levels males >800, females >1,000 ng/

**Intervention:** Structured treatment of HF according to guidelines with or without NT-proBNP monitoring

- Target: At least a 50% reduction from BL NT-proBNP

**1st endpoints:** Composite endpoint of d alive, d out of hospital and symptom score

**Results:** There were no differences between the groups concerning either the 1st endpoint (p=0.28) or its components (CV death, p=0.93; CV hospitalization, p=0.88; or symptom score, p=0.28)

- Treatment doses of beta blockers and RAS blockers were markedly increased towards target doses a similar degree in both groups

---

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
### STARBRITE Trial

**Aim:** Whether outpatient diuretic management guided by BNP and clinical assessment better compared with clinical assessment alone

**Study Type:** Multicenter (3) RCT

**Size:** 130

**Inclusion criteria:** Hospitalized HF pts with LEVF $\leq$ 35%

**Exclusion criteria:** Serum creatinine $>$ 3.5 mg/dL and ACS

**Intervention:** Outpatient post discharge BNP and clinical assessment guided therapy

**Comparator:** Clinical assessment alone.

**1° endpoints:** Composite endpoint of d alive and d out of hospital,

**Results:** No significant difference HR: 0.72; 95% CI: 0.41–1.27; p=0.25

- Change in serum creatinine, or change in SBP not different
- BNP strategy pts received significantly more ACE inhibitors, beta blockers

### PROTECT Study

**Aim:** Whether elders benefit from NP-guided HF care

**Study Type:** Single center RCT

**Size:** 151

**Inclusion criteria:** Chronic HF pts with LV systolic dysfunction

**Intervention:** Management guided by NT-proBNP with a goal to lower NT-proBNP $\leq$ 1000 pg/mL over 10 mo

**Comparator:** Standard of care

**1° endpoints:** Total CV events in 2 age categories 75 and $\geq$ 75 y

**Results:** Pts $\geq$ 75 y with NT-proBNP management had lowest rate of CV events (1.76 events per pt with standard of care vs. 0.71 events per pt with NT-proBNP guide, p=0.03)

- Improvement in QoL, LVEF, and indices of LV volume with guided approach
- NP guidance changed therapy: greater use of aldosterone antagonists and lesser use of loop diuretics in the guided therapy group (no difference in ACE inhibitors or beta blockers)

### UPSTEP-study

**Aim:** To determine whether BNP-guided HF treatment improves morbidity and/or mortality

**Inclusion criteria:** Ambulatory HF NYHA II-IV, LVEF $<40\%$ and elevated BNP levels

**Intervention:** BNP-guided (BNP) with a goal $<150$ or $300$ ng/L for elderly

**Comparator:** Conventional (CTR) HF treatment

**1° endpoints:** Combined death and worsening/hosp for HF

**Results:** No significant differences 1° outcome (p=0.18)

- No differences for d out of hospital, and younger vs. elderly.
- Subgroup analysis: improved survival ($p<0.0001$ for the 1° outcome) among responders with $>30\%$ decrease in BL BNP value vs. nonresponders.
### 2017 Heart Failure Focused Update Data Supplement

| Study Type: | Multicenter RCT-probe design |
| Size: | 279 |
| Aim: | To validate and characterize the use of BNP in the diagnosis of HF in pts with dyspnea |
| Study type: | Prospective, blinded, diagnostic accuracy study |
| Size: | 1,856 |
| Inclusion criteria: | Pts who came to the emergency department with acute dyspnea |
| Exclusion criteria: | Age <18 y and those whose dyspnea was clearly not secondary to HF (i.e., those with trauma or cardiac tamponade), acute myocardial infarction, unstable angina, or renal failure |
| Intervention: | Comparisons of BNP values among diagnostic groups including HF and non HF pts |
| Comparator: | Non-HF pts such as pulmonary disease, cor pulmonale |
| 1<sup>st</sup> endpoint: | Diagnostic accuracy of BNP at a cutoff of 100 pg/mL was 83.4%. The negative predictive value of BNP <50 pg/mL was 96% |
| Secondary endpoint: | In multiple logistic-regression analysis, measurements of BNP added significant independent predictive power to other clinical variables in models predicting which pts had HF |

*Used in conjunction with other clinical information, rapid measurement of BNP is useful in establishing or excluding the diagnosis of acute HF failure in pts with acute dyspnea*

| Aim: | To analyze the role of NT-pro-BNP in diagnosis of HF in pts presenting with dyspnea, the so-called natriuretic peptide gray zone. NT-pro-BNP concentrations, clinical characteristics, and 60-d mortality were studied in acutely dyspneic pts from an international |
| Inclusion criteria: | Acutely dyspneic pts |
| Exclusion criteria: | With trauma or cardiac tamponade, acute myocardial infarction, unstable angina, or renal failure |
| Intervention: | Comparisons of NT-pro-BNP among diagnostic groups including HF and non-HF pts |
| Comparator: | Non-HF pts such as pulmonary disease, cor pulmonale |
| 1<sup>st</sup> endpoint: | Subjects with HF and diagnostically elevated NT-pro-BNP concentrations had the highest mortality rates, subjects without HF and NT-pro-BNP concentrations < 300 ng/L had the lowest mortality rates, and subjects with gray-zone NT-pro-BNP had intermediate outcomes, irrespective of their final diagnoses |

*Adding specific clinical information to NT-pro-BNP improves diagnostic accuracy in subjects with intermediate NT-pro-BNP concentrations. Mortality rates in subjects with intermediate NT-pro-BNP concentrations are lower than in those with NT-pro-BNP concentrations diagnostic for HF but are higher than in subjects with NT-pro-BNP concentrations less than the gray zone*
### Maisel et al. 2004 (25) 15364340

**Aim:** To examine the relationships among BNP levels and HF severity, clinical decision making, and outcomes

**Study type:** Multicenter, prospective, blinded, diagnostic accuracy study

**Size:** 1,256

**Inclusion criteria:** Pts over the age of 18 presenting to the ED with HF and who received treatment in the ED or hospital admission for HF were included.

**Exclusion criteria:** Current MI or ACS with ST-segment deviation of ≥1 mm, renal failure requiring dialysis, or pts with a baseline BNP concentration of ≤100 pg/mL were excluded.

**Intervention:** Physicians were blinded to the actual BNP level and subsequent BNP measurements.

**Comparator:** Comparison between severity of HF determined by physicians or BNP and outcomes

**1st endpoint:** ED doctor's intention to admit or discharge a pt had no influence on 90-d outcomes, while the BNP level was a strong predictor of 90-d outcome. The 90-d combined event rate (HF visits or admissions and mortality) in the group of pts admitted with BNP <200 pg/mL and >200 pg/mL was 9% and 29%, respectively (p=0.006).

- In pts presenting to the ED with HF, there is a disconnect between the perceived severity of HF by ED physicians and severity as determined by BNP levels. The BNP levels can predict future outcomes and thus may aid physicians in making triage decisions about whether to admit or discharge pts. Emerging clinical data will help further refine biomarker-guided outpatient therapeutic and monitoring strategies involving BNP.

### O'Connor et al. 2010 (26) 20185037

**Aim:** To identify high-risk HF pts at hospital discharge

**Study type:** Predictive modeling using variables obtained during hospitalization in the ESCAPE trial

**Derivation cohort:** ESCAPE trial, n=423

**Validation cohort:** FIRST trial, n=471

**Inclusion criteria:** Hospitalized with severe HF, LVEF ≤30%, SBP ≤125 mmHg.

**Exclusion criteria:** Creatinine >3.5 mg/dL, prior inotrope use

**1st endpoint:**
- 6-mo mortality and death or rehospitalization rates (64%)
- Multivariate discharge predictors of death included: BNP, per doubling (HR: 1.42), cardiac arrest or mechanical ventilation, yes/no (HR: 2.54), BUN, per 20 mg/dL increase (HR: 1.22) and sodium, per unit mEq/L increase (HR: 0.93)

- A simplified discharge score discriminated mortality risk from 5% (score=0) to 94% (score=8).
- Bootstrap validation demonstrated good internal validation for the model (c-index 0.78).
- Limitations: ESCAPE represented pts with severe LV dysfunction and advanced symptoms (not the general population of acute HF) managed at experienced centers; exclusion of pts with characteristics...
Data Supplement B. Nonrandomized Trials/ Observational Studies/ Registries for Changes in or Discharge NP Levels in ADHF – Biomarkers (Section 6.3)

### Aim:
To compare 18 mo outcomes of NT-BNP-guided vs. symptom guided HF therapy

**Study type:** Prospective cohort single center study

**Size:** 182 pts

**Inclusion criteria:** Consecutive ADHF pts defined by ESC or Framingham criteria

**Follow up:** 6 mo

**1° endpoints:**
- Death or readmission

**Results:**
- Pts were classified into 3 groups: (1) decreasing NT-proBNP levels by at least 30% (n=82), (2) no significant modifications on NT-proBNP levels (n=49), and (3) increasing NT-proBNP levels by at least 30% (n=25).
  - Among the 64 pts discharged without volume overload, a positive association between change in NT-proBNP and outcome was observed (HR: 2.66; 95% CI: 0.77–9.18 for change <30%; HR: 16.04; 95% CI: 9.49–52.02 for increase ≥30% compared with those with decreasing NT-proBNP by at least 30%)
  - Pts demonstrating a ≥30% increase in NT-proBNP levels during the course of their admission had the most adverse prognosis

- Study relatively old and small

---

### Kociol et al. 2013 (30) 23250981

**Aim:** Examine relationship between markers of decongestion and symptom relief and clinical outcomes

**Study type:** retrospective analysis of the RCT, DOSE-AHF

**Size:** 308 pts

**Inclusion criteria:** Pts enrolled in DOSE-AHF

**Follow up:** 60 d

**1° endpoints:**
- Time to death, first rehospitalization or emergency department visit

**Results:**
- Of the weight loss, fluid loss, and NT-proBNP reduction, only % reduction in NT-proBNP was significantly associated with symptom relief (r=0.13; p=0.04).
  - Reduction in NT-proBNP Associated with better outcome (NT-proBNP HR: 0.95; 95% CI: 0.91–0.99 per 10% reduction).
  - Favorable changes in each of the 3 markers of decongestion were associated with improvement in time to death, rehospitalization, or emergency department visit at 60 d

---

### Kociol et al. 2011 (31) 21743005

**Aim:** To examine if admission, discharge, or change from admission to discharge BNP measure is the most important predictor of long-term outcomes

**Inclusion criteria:** Linked pts ≥65 y of age from hospitals in OPTIMIZE-HF to Medicare claims

**Follow up:** 1 y

**1° endpoints:**
- The discharge BNP had the best performance and was the most important characteristic for predicting 1 y mortality (HR for log transformation: 1.34; 95% CI: 1.28–1.40) and 1 y death or rehospitalization (HR: 1.15; 95% CI: 1.12–1.18).

- Compared with a clinical variables, discharge BNP model improved risk reclassification and discrimination in predicting each outcome (1 y mortality: NRI: 5.5%, p<0.0001; IDI: 0.023, p<0.0001; 1-y mortality or rehospitalization: NRI: 4.2%, p<0.0001; IDI: 0.010, p<0.0001)

### Son et al. 2012
(43) 22564550

#### Study type:
Observational, decision making model using rough set and decision tree approaches

#### Inclusion criteria:
- ED presentation for dyspnea (HF vs. Noncardiac control)
- Complete medical records

#### Exclusion criteria:
- HF excluded if other diagnosis made

#### Size:
159 subjects (71 HF, 88 control)

#### 1° endpoint:
HF diagnosis

#### Results:
NT-proBNP had utility beyond the history and physical for diagnosing HF among primary care outpatients presenting with signs/symptoms of HF

---

### Kelder et al. 2011
(44) 22104551

#### Study type:
Cross-sectional, diagnostic accuracy (observational)

#### Inclusion criteria:
Pts presenting with signs/symptoms of HF who were referred to 1 of 8 rapid access clinics in the Netherlands

#### Exclusion criteria:
Known, established HF
Acute HF requiring immediate therapeutic intervention

#### Size:
721 subjects

#### 1° endpoint:
Diagnosis of HF

#### Results:
- 207/721 (29%) had HF
- C-statistic without proBNP =0.83
- C-statistic with proBNP =0.86
- NRI 69%

---

### Booth et al. 2014
(45) 24969534

#### Study type:
Systematic review

#### Inclusion criteria:
- Pts presenting with signs or symptoms of HF or were at risk of HF a time of presentation
- Primary care setting

#### Exclusion criteria:
Studies with subjects with:
- Age <18 y
- Acute HF
- Known exacerbation of chronic stable HF

#### Size:
12 BNP publications; 20 NT-proBNP publications

#### 1° endpoint:
Diagnostic accuracy of BNP or NT-proBNP

#### Results:
- BNP pooled sensitivity (lowest cutpoint 0.85, optimal 0.8, manufacturer 0.74) and specificity (0.54, 0.5, 0.58, respectively)
- NT-proBNP pooled sensitivity (lowest cutpoint 0.90, optimal 0.86, manufacturer 0.82) and specificity (0.5, 0.58, 0.58, respectively)

#### Both BNP and NT-proBNP have good diagnostic utility for diagnosing HF in the primary care setting in those with signs/symptoms of HF or at risk of developing HF
- Tests have better sensitivity than specificity
- Authors felt that it was unlikely that further studies will change these conclusions

### Zairis et al. 2010 (50) 19157603

**Aim:** To investigate the combined prognostic value of admission serum levels of BNP, cTnI and hs-CRP, in pts hospitalized because of acutely decompensated severe (NYHA class III/IV) low-output chronic HF.

**Study type:** Multicenter Prospective cohort

| Inclusion criteria: | Consecutive hospitalized acute decompensated HF pts with NYHA class III/IV recruited in the 5 participating centers |
| Exclusion criteria: | Competing diagnoses of renal failure, MI |

**1° endpoint:** Cardiac mortality by 31 d

**Results:**
There was a significant gradual increased risk of 31-d cardiac death with increasing in the number of elevated biomarkers (p<0.001). By multivariate Cox regression analysis, elevated serum levels of BNP (p=0.002), cTnI (p<0.001) and hs-CRP (p=0.02) were independent predictors of the study end point.

- In pts hospitalized for acute decompensation of severe (NYHA III/IV) low-output HF, BNP, cTnI and hs-CRP upon admission offers enhanced early risk stratification.

### Peacock et al. 2008 (51) 18480204

**Aim:** Describe the association between elevated cardiac troponin levels and adverse events in hospitalized pts with acute decompensated HF

**Study type:** Registry analysis

| Inclusion criteria: | Hospitalizations for acute decompensated HF between 2001 and 2004 in ADHERE. Entry criteria included a troponin level that was obtained at the time of hospitalization |
| Exclusion criteria: | Pts with a serum creatinine level ≥ 2.0 mg per deciliter |

**1° endpoint:** Overall, 4,240 pts (6.2%) were positive for troponin.

**Results:**
Pts who were positive for troponin had lower SBP on admission, a lower EF, and higher in-hospital mortality (8.0% vs. 2.7%, p<0.001) than those who were negative for troponin. The adjusted odds ratio for death in the group of pts with a positive troponin test was 2.55 (95% CI: 2.24–2.89; p<0.001)

- In pts with acute decompensated HF, a positive cardiac troponin test is associated with higher in-hospital mortality, independently of other predictive variables.
Lee et al. 2012 (52) 22665814

**Aim:** To derive and validate a model for acute HF mortality applicable in the ED.

**Size:** 12,591

**Study type:** Multicenter Registry analysis

**Inclusion criteria:** Population-based random sample of 12,591 pts presenting to the ED from 2004 to 2007

**Exclusion criteria:** No lab availability

**1° endpoint:** Death within 7 d of presentation

**Results:**
- Mortality risk increased with higher triage heart rate (OR: 1.15; [95% CI: 1.03–1.30] per 10 beats/min) and creatinine concentration (OR: 1.35; [CI: 1.14–1.60] per 1 mg/dL [88.4 micro mol/L]), and lower triage SBP (OR: 1.52 [CI: 1.31–1.77] per 20 mm Hg) and initial oxygen saturation (OR, 1.16 [CI: 1.01–1.33] per 5%).

**Aim:** A multivariate index comprising routinely collected variables stratified mortality risk with high discrimination in a broad group of pts with acute HF presenting to the ED.

---

Dhaliwal et al. 2009 (53) 19398076

**Aim:** Compare the relationship between absolute and relative changes in BNP with future clinical events, and whether serial BNP measurements add prognostic information in pts treated for decompensated HF

**Size:** 203

**Study type:** Retrospective registry analysis

**Inclusion criteria:** Pts hospitalized for acute decompensated HF by Framingham criteria

**Exclusion criteria:** Renal failure, severe lung disease, acute coronary syndrome

**1° endpoint:** For the combined end point of total mortality or readmission for HF

**Results:**
- Increasing tertiles of BNP levels after treatment had a hazard ratio of 1.4 (1.1–1.7, p<0.01) and increasing tertiles of percent reduction in BNP, had a HR:0.7 (0.6–0.9; p=0.005), respectively, for the combined end point of total mortality or readmission for HF
- Follow-up BNP performed better than did baseline BNP or percent reduction in BNP.
- More BNP measurements other than the follow-up BNP did not improve the fit of the model further.
- Both lower absolute BNP levels and greater percentage reduction in BNP with treatment of decompensated HF are associated with better event-free survival.
- Advocating a threshold BNP to which pts should be treated may not be possible given that high BNP levels tend not to decrease to levels associated with better outcomes during the short period of treatment.
- More BNP measurements do not add prognostic information beyond that provided by a single BNP level after treatment

---

Alonso-Martinez et al. 2002 (54) 12034159

**Aim:** To determine usefulness of CRP in predicting need for readmission in HF

**Size:**

**Inclusion criteria:** Intervention group: admission with HF; control group: admission with syncope

**1° endpoint:** 18-mo HF readmission

- CRP levels were higher in pts with HF compared to syncope (3.94 vs. 0.84, p=0.0007)

**Limitation:** small, single-center

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
## Study type:
- Observational

### Size:
- 76

#### Exclusion criteria:
- Clear cause for elevated CRP (e.g., inflammation, infection)
- Higher CRP levels were associated with higher NYHA class, increased risk of HF readmission, shorter time to readmission, and increased mortality

#### Safety endpoint:
- NYHA class on discharge and death

#### 1° endpoint:
- All-cause mortality at 1 y
  - 25% died within 1 y
  - At baseline, decedents (n=62) had higher median plasma concentrations of all 10 biomarkers than survivors (n=189)
  - In multivariate model, only MR-proANP (RR: 1.6), ST2 (RR: 1.7) and CgA (RR: 1.5) were independent predictors of death
  - Low systolic BP and advanced age were also independent predictors of 1-y mortality

#### Limitations:
- Post-hoc analysis; subgroup (87 of 251) had dyspnea due to acute HF alone; single-center, majority men (94%)

---

### Dieplinger et al. 2010

#### Aim:
- To evaluate the prognostic value of established and novel biomarkers in pts with acute dyspnea

#### Study type:
- Observational

#### Size:
- 251

#### Inclusion criteria:
- Pts presenting to ED with acute dyspnea

#### Exclusion criteria:
- STEMI, NSTEMI or ACS troponin pos.

#### Biomarkers on admission and 48 hours:
- BNP, MR-proANP, MR-proADM, copeptin, C-terminal pro-ET-1, soluble ST2, chromogranin A (CgA), adiponectin, proguanylin, prouroguanylin

#### Safety endpoint:
- NYHA class on discharge and death

#### 1° endpoint:
- All-cause mortality at 1 y
  - 25% died within 1 y
  - At baseline, decedents (n=62) had higher median plasma concentrations of all 10 biomarkers than survivors (n=189)
  - In multivariate model, only MR-proANP (RR: 1.6), ST2 (RR: 1.7) and CgA (RR: 1.5) were independent predictors of death
  - Low systolic BP and advanced age were also independent predictors of 1-y mortality

#### Limitations:
- Post-hoc analysis; subgroup (87 of 251) had dyspnea due to acute HF alone; single-center, majority men (94%)

---

### Ilva et al. 2008

#### Aim:
- To evaluate prevalence and prognostic significance of elevated cTnI and cTnT in acute HF

#### Study type:
- Observational substudy

#### Size:
- 364

#### Inclusion criteria:
- Hospitalized with acute HF

#### Exclusion criteria:
- ACS pts; missing sample for cardiac TnI/TnT

#### Biomarkers on admission and 48 hours:
- cTnT, cTnI, cystatin C, NT-proBNP

#### 1° endpoint:
- 6-mo mortality
  - 51% of pts had +cTnl and 30% had +cTnT
  - 6-mo all-cause mortality was 18.7%
  - Both cTnl (OR: 2.0; 95% CI: 1.2–3.5) and cTnT (OR: 2.6; 95% CI: 1.5–4.4) were associated with adverse outcome in pts with previous, but no de novo HF

- On multivariable analysis, cystatin C (OR: 6.3; 95% CI: 3.2–13), logNT-proBNP (OR: 1.4; 95% CI: 1.0–1.8) and SBP on admission (10 mm Hg increase; OR: 0.9; 95% CI: 0.8–0.9) were independent risk predictors, whereas troponins were not

- Mortality was proportional to troponin release

#### Limitations:
- Exclusion of pts with ACS was based on clinician judgment; cut-off values for troponins was based on 2000 ESC/ACC guidelines

---

### Januzzi et al. 2007

#### Aim:
- To examine the value of measuring ST2 in pts

#### Study type:
- Observational

#### Size:
- 17692745

#### Inclusion criteria:
- Pts presenting to ED with acute dyspnea

#### 1° endpoint:
- death at 1 y
  - ST2 levels were significantly higher in pts

- ST2 levels were higher in pts with HF/EF (0.67 ng/ml; IQR 0.31–1.50) vs. HFpEF (0.42 ng/ml; IQR 0.22–
### Manzano-Fernandez et al. 2011

**Aim:** To determine whether risk of mortality associated with ST2 differs in pts with acute HFpEF vs. HFpEF

**Study type:** Observational study combining 3 databases (Boston, MA; Linz, Austria; Murcia, Spain)

**Size:** 447

**Inclusion criteria:** Acute HF

**Exclusion criteria:** N/A

**Biomarkers:** ST2, troponin T, NT-proBNP, CRP

**1° endpoint:**
- 1 y vital status
- During 1-y follow-up, 117 pts (26%) died
- ST2 levels were higher among deceased than survivors (median 0.80 ng/ml vs. 0.38 ng/ml; p<0.001); and this pattern was true for HFpEF and HFpEF
- On multivariate analysis, elevated ST2 levels were associated with greater risk of 1-y mortality for HFpEF (HR: 1.41; 95% CI: 1.14–1.76) than HFpEF (HR: 1.20; 95% CI: 1.10–1.32)

**Limitations:** pooled multinational analysis that lacked predefined endpoints and complete echocardiographic measures; no pre-discharge ST2 levels

| ST2, troponin T, NT-proBNP, CRP | Acute HF | N/A | ROC curves and multivariable Cox proportional hazards analyses
- ST2 levels correlated with severity of HF (p<0.001), LVEF and creatinine clearance
- ST2 levels correlated with BNP, NT-proBNP and CRP
- In a multivariable model, ST2 remained a predictor of mortality (HR: 2.04; 95% CI: 1.30–3.24)

### Rehman et al. 2008

**Aim:** To examine patient-specific characteristic of ST2 in pts with acute HF

**Study type:** Observational study combining 2 databases (Boston, MA; Linz, Austria)

**Size:** 346

**Inclusion criteria:** Acute HF

**Exclusion criteria:** N/A

**Biomarkers:** ST2, BNP, NT-proBNP, CRP

**1° endpoint:**
- ROC curves and multivariable Cox proportional hazards analyses
- ST2 levels correlated with severity of HF (p<0.001), LVEF and creatinine clearance
- ST2 levels correlated with BNP, NT-proBNP and CRP
- In a multivariable model, ST2 remained a predictor of mortality (HR: 2.04; 95% CI: 1.30–3.24)

**Limitations:** lack of serial measures of ST2; biologic role of ST2 in acute HF poorly understood

### Study Acronym; Author; Year Published

### Aim of Study; Study Type; Study Size (N)

### Patient Population

- Informed consent
- Age ≥18
- Stable (>3 mo) symptomatic HF (NYHA class II–IV HF)
- Decreased LVEF <40
- ≥4 wk dose of ACE inhibitors
- Seated SBP ≥90 mm Hg

### Exclusion criteria:

- Uncontrolled hypertension
- Acute coronary events within 3 mo
- Revascularization within 3 mo
- Serum potassium <3.5 or >5.3 mmol/L
- Creatinine >221 μmol/L
- Transaminases >2 upper limit of normal
- Leucocytes <3.0x10⁹/L, neutrophils <1.5x10⁹/L, or platelets <120x10⁹/L

### Intervention:

- Omapatrilat (289) target dose 40 mg daily

### Comparator:

- Lisinopril (284) target dose 20 mg daily

### Endpoint Results (Absolute Event Rates, P values; OR or RR; & 95% CI)

#### 1st endpoint: Change in exercise duration from baseline to wk 12

- 10968433

#### 2nd endpoint:

- No difference in combined endpoint of death and admission for worsening HF (p=0.52)
- Combined endpoint of death and comorbidity for worsening HF was better for omapatrilat HR: 0.52 (95% CI: 0.28–0.96; p=0.035)
- Angioedema occurred in no pts taking omapatrilat vs. 1 taking enalapril

### Comments:

Vasopeptidase inhibitor omapatrilat did not improve exercise tolerance compared with ACE inhibitor lisinopril

### SHEP HF Results

**Kostis et al. 1997**

- **Aim:** To assess the effect of antihypertensive treatment in isolated systolic HTN
- **Study type:** RCT
- **Size:** 4,736

**Inclusion criteria:**
- Age > 60,
- SBP 160–219,
- DBP < 90

**Exclusion criteria:**
- Recent MI or CABG,
- pts with DM,
- stroke, AF

**Intervention:**
- Antihypertensive therapy: step 1, chlorthalidone,
- step 2, atenolol (2,365)

**Comparator:**
- Placebo (2,371)

**1° endpoint:**
- Incident HF
- Active treatment decreased BP from mean of 170/77 to mean of and decreased HF events from 105 (4.4%) with placebo to 55 (2.3%) RR: 0.51 (95% CI: 0.37–0.71, p<0.001) at 4.5 y
- LV function was not measured

**Results of SHEP showed decreased stroke risk with active treatment 149 (8.2%) with placebo to 96 (5.4%) RR: 0.64 (95% CI: 0.49–0.82, p=0.003) at 4.5 y**

### CHARM-Preserved

**Yusuf et al. 2003**

- **Aim:** To ascertain efficacy of candesartan in pts with HFpEF.
- **Study type:** RCT
- **Size:** 3,023

**Inclusion criteria:**
- HF pts in NYHA class II-IV with EF > 40%

**Exclusion criteria:**
- Creatinine > 2.65 μmol/L (3.0 mg/dL),
- potassium > 5.5 mmol/L,
- MI, stroke, or open-heart surgery in the previous 4 wk

**Intervention:**
- Candesartan (1,514)

**Comparator:**
- Placebo (1,509)

**1° endpoint:**
- CV death or admission for HF.
- No difference for candesartan 333 (22%) vs. placebo 366 (24%) at 3.5 y, HR: 0.89; 95% CI: 0.77–1.03; p=0.12) covariate adjusted HR: 0.86 (95% CI: 0.74–1.00); p=0.051)
- No differences for 2° endpoints except for covariate adjusted risk of HF admission HR: 0.84 (95% CI: 0.70–1.00; p=0.047). CV death 11.2 vs. 11.3% HR: 0.99 (95% CI: 0.80–1.22; p=0.918).
- Adverse effects requiring discontinuation: hypotension (2.4 vs. 1.1%; p=0.009; increased creatinine, 4.8 vs. 2.4%; p=0.005; hyperkalemia 1.5 vs. 0.6%; p=0.029)
- Limitations: Some pts may have had previous EF <40%

### PEP-CHF

**Cleland et al. 2003**

- **Aim:** To ascertain efficacy of perindopril in pts with HFpEF.
- **Study type:** RCT
- **Size:**

**Inclusion criteria:**
- Age ≥ 70,
- Rx with diuretics for clinical diagnosis of HF,
- echo criteria for diastolic dysfunction

**Exclusion criteria:**
- Perindopril (424)

**Comparator:**
- Placebo (426)

**1° endpoint:**
- All-cause mortality or admission for HF.
- No difference for perindopril 107 (25.1%) vs. placebo 131 (23.6%) at 3 y, HR: 0.92; 95% CI: 0.70–1.21; p=0.5.
- HF hospitalization lower at 1 y with perindopril: 34 events (8.0%) vs. placebo 53 (12.4%), HR: 0.63; 95% CI: 0.41–0.97; p=0.033).
- Limitations: Many pts withdrew (40% by 18 mo), often to take open-label ACE inhibitors (36% by study end).

<tbody>
<tr>
<td>Xie et al. 2016 (89) 26559744</td>
<td>Aim: To assess the efficacy and safety of intensive BP lowering strategies.</td>
<td>Inclusion Criteria: RCTs with different BP targets or different BP changes between more vs. less intense therapy with at least 6 mo follow-up. Exclusion Criteria: Trials that did not assess a different target or relevant outcome.</td>
<td>5 RCTs (6,960 pts) enrolled only pts with DM and 6 trials (2,809 pts) specifically recruited pts with CKD.</td>
<td>1º Outcomes: Major CV events, defined as MI, stroke, HF or CV death, separately and combined; nonvascular and all-cause mortality; ESRD; and adverse events; new onset microalbuminuria/macroalbuminuria or change from micro- to macroalbuminuria and retinopathy in pts with DM. Results: Pts in the more intensive BP-lowering treatment group had mean BP 133/76 mm Hg compared with 140/81 mm Hg in the less intensive group. Intensive BP-lowering treatment achieved RR reductions for major CV events: 14% (95% CI: 4, 22), MI: 13% (95% CI: 0, 24), stroke: 22% (95% CI: 10, 32), albuminuria: 10% (95% CI: 3, 16), and retinopathy progression: 19% (95% CI: 0–34). However, more</td>
<td>Study Limitations: Only 6,960 pts with DM were included in the total study size of 44,989 pts. Conclusions: The absolute CV benefits were greatest in trials in which all enrolled pts had vascular disease, renal disease or DM. However, only 6,960 of the 44,989 pts had DM and no subanalysis for DM was provided; however, the outcome benefits were qualitatively most striking for pts with DM, CKD and/or vascular disease.</td>
</tr>
</tbody>
</table>
intensive treatment had no clear effects on HF: RR: 15% (95% CI: -11, 34), CV death: 9% (-11, 26), total mortality: 9% (95% CI: -3, 19), or ESRD: 10% (95% CI: -6, 23). The reduction in major CV events was consistent across pt groups, and additional BP lowering had a clear benefit even in pts with SBP <140 mm Hg. The absolute benefits were greatest in trials in which all enrolled pts had vascular disease, renal disease, or DM. Serious adverse events associated with BP lowering were only reported by 6 trials and had an event rate of 1.2% per y in intensive BP lowering group pts, compared with 0.9% in the less intensive treatment group (RR: 1.35 (95% CI: 0.93, 1.97)). Severe hypotension was more frequent in the more intensive treatment regimen (RR: 2.68 (95% CI: 1.21, 5.89), p=0.015), but the absolute excess was small (0.3% vs. 0.1% per pt-y for the duration of follow-up).

### SPRINT
Wright et al. 2015
(90) 26551272

**Aim:** To test the effectiveness of a goal SBP <120 mm Hg vs. a goal SBP <140 mm Hg for the prevention of CVD in pts with SBP ≥130 mm Hg at BL.

**Study type:**

**Inclusion criteria:**
- SBP ≥130 mm Hg, with upper limit varying as number of pre-trial BP-lowering meds increased.
- Age ≥50 y
- Presence of at least 1:
  - Clinical or subclinical CVD

**Intervention:**
- Intensive BP lowering treatment to goal SBP <120 mm Hg (4,678)

**Comparison:**
- Standard BP lowering treatment to goal SBP <140 mm Hg (4,678)
- Net treatment difference ~3 drugs (2.8) on average vs. 2 drugs (1.8) on

**1° Endpoint:**
- Composite of MI, non-MI ACS, stroke, ADHF, CV death; HR: 0.75 (95% CI: 0.64, 0.89)
- Lower BP target reduced composite outcome 243 pts (1.65%/y) vs. higher target 319 (2.19%/y), HR: 0.75; 95% CI: 0.64–0.89; p<.001) and death: lower target 155 vs. 201, HR: 0.73; 95% CI: 0.60–0.90;

**Summary:**
- More intensive SBP lowering to a goal of <120 mm Hg with achieved mean of ~121 mm Hg resulted in less CVD and lower total mortality over 3.26 y in comparison with a goal SBP <140 mm Hg and achieved SBP of ~135 mm Hg.
- There were small increases in some expected SAEs. Perhaps unexpected, a sizable increase
**RCT**

**Size:**
- 9361 pts followed
- median of 3.26 y.

**Exclusion criteria:**
- CKD stage 3 or greater
- Age ≥75
- Framingham General CVD risk ≥15% in 10 y

**During the trial, mean SBP was 121.5 vs. 134.6.**

**Other endpoints:**
- Total deaths HR: 0.73 (95% CI: 0.60–0.90)
- 1° or death HR: 0.78 (95% CI: 0.67–0.90)
- Components of 1° composite mostly consistent in direction other than ACS – no difference.

**CKD outcomes:**
- 1° in CKD pts: reduction in GFR of ≥50% or ESRD HR: 0.89 (95% CI: 0.42, 1.87)
- Incident albuminuria HR: 0.72 (95% CI: 0.48, 1.07)
- In pts without CKD: reduction in GFR ≥30% and to <60 HR: 3.49 (95% CI: 2.44–5.10)
- Incident albuminuria HR: 0.81 (95% CI: 0.63–1.04)

**Adverse events:**
- SAEs: 1.04, p=0.25
- Significant absolute increases seen in intensive group for hypotension (1%), syncope (0.6%), electrolyte abnormality (0.8%), AKI/ARF (1.6%) over the study period.
- 1.7% fewer pts had orthostatic hypotension in intensive group, p=0.01.

**Limitations:**
- Few pts were untreated at BL ~9%, so SPRINT provides little if any insight at present regarding BP lowering medication initiation for untreated people with SBP 130–139.
### SPRINT Senior Williamson et al. 2016 (91) 27195814

**Aim:** Intensive SBP goal <120mmHg vs standard (SBP goal <140)

**Study Type:** RCT

**Size:** 2,636

30% met criteria for being classified as ambulatory frail

**Mean follow-up:** 3.1 y

**Inclusion:** Men and women age 75+; mean age 79.8 y; 38% women; 17% black, 74% Caucasian; Exclusions: Nursing home residents; diabetes, Stroke, symptomatic HF in past 6 mo or EF <35%, dx or treatment of dementia, unintentional wt loss >10% in past 5 mo. SBP<110 after standing 1 min, expected survival <3y

**Intervention:** Medications and dietary advice to achieve SBP of <120 mm Hg

**Comparator:** Medications and dietary advice to achieve SBP of <140 mm Hg

**Achieved SBP:**
- Intensive= 123.4 mm Hg
- Standard= 134.8 mm Hg

**1 endpoint:** Composite CVD outcome (AMI, non-MI ACS, Stroke, HF, CVD death)

**Results:** 102 events in the intensive treatment group vs 148 events in the standard treatment group; HR: 0.66; 95%CI: 0.51–0.85 and all-cause mortality (73 deaths vs. 107 deaths, respectively; HR: 0.67; 95%CI: 0.49–0.91. No significant difference in falls, orthostatic hypotension, or overall SAEs.

**NNT for primary outcome=27 and NNT for all-cause mortality=41**

**Limitations:** Does not apply to nursing home patients or those with dementia

**Conclusions:** Intensive SBP is safe and effective for lowering CVD events and total mortality in persons age 75 and older

---

### TOPCAT Regional Analysis Pfeffer et al. 2015 (84) 25406305

Post-hoc analysis that captures differences in outcomes by geography

**Aim:** To assess regional differences in the effects of spironolactone in pts with HFpEF.

**Study Type:** RCT

**Size:** 3,445

**Inclusion criteria:** Symptomatic HF, Age ≥50y, LVEF ≥45% stratified according to
- HF Hospitalization within past y
- Elevated NPs

**Exclusion criteria:** Renal disease (eGFR <30 or creatinine >22 μmol/L (2.5 mg/dL), systemic illness with life expectancy <3 y, Specific co-existing

**Intervention:** Spironolactone (1,722)

**Comparator:** Placebo (1,723)

**1ª endpoint and results:**
- Composite of CV mortality, HF hospitalization, or aborted cardiac arrest across regions.
- 1ª outcome events in 522 (29.5%) pts in the Americas and 149 (8.9%) in Russia/Georgia. 1ª outcome event rates with spironolactone and placebo 10.4/100 pt y and 12.6/100 pt y in the Americas and 2.5/100 pt y and 2.3/100 pt y in Russia/Georgia. HR spironolactone vs. placebo 0.82; 95% CI: 0.69–0.98; p=0.026) in the Americas and 1.10 95% CI: 0.79–1.51; p=0.12) in Russia/Georgia.

- Spironolactone had markedly greater effects on BP (4.2 mm Hg drop vs. 0.6 mm Hg; p<0.001, potassium change relative to placebo (0.26 mmol/L vs. 0.08 mmol/L), and increase in creatinine (0.10 vs. 0.02 mg/dL; p<0.001)

**Limitations: post-hoc analysis**

<table>
<thead>
<tr>
<th>Law et al., 2009 (92) 19454737</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Study type:</strong> Meta-analysis of use of BP lowering drugs in prevention of CVD from 147 randomized trials</td>
</tr>
<tr>
<td><strong>Size:</strong> Of 147 randomized trials of 464,000 pts, 37 trials of beta blockers in CAD included 38,892 pts, and 37 trials of other antihypertensive drugs in CAD included 85,395 pts</td>
</tr>
<tr>
<td><strong>Inclusion criteria:</strong> The database search used Medline (1966-Dec. 2007 in any language) to identify randomized trials of BP lowering drugs in which CAD events or strokes were recorded. The search also included the Cochrane Collaboration and Web of Science databases and the citations in trials and previous meta-analyses and review articles.</td>
</tr>
<tr>
<td><strong>Exclusion criteria:</strong> Trials were excluded if there were &lt;5 CAD events and strokes or if treatment duration was &lt;6 mo.</td>
</tr>
<tr>
<td><strong>1st endpoint:</strong> CAD events; stroke</td>
</tr>
<tr>
<td><strong>Results:</strong> In 37 trials of pts with a history of CAD, beta blockers reduced CAD events 29% (95% CI: 22%–34%). In 27 trials in which beta blockers were used after acute MI, beta blockers reduced CAD events 31% (95% CI: 24%–38%), and in 11 trials in which beta blockers were used after long term CAD, beta blockers insignificantly reduced CAD events 13%. In 7 trials, beta blockers reduced stroke 17% (95% CI: 1%–30%). CAD events were reduced 14% (95% CI: 2%–25%) in 11 trials of thiazide diuretics, 17% (95% CI: 11%–22%) in 21 trials of ACE inhibitors, insignificantly 14% in 4 trials of angiotensin receptor blockers, and 15% (95% CI: 8%–22%) in 22 trials of CCBs. Stroke was reduced 38% (95% CI: 28%–47%) in 10</td>
</tr>
</tbody>
</table>

- With the exception of the extra protective effect of beta blockers given shortly after a MI and the minor additional effect of CCBs in preventing stroke, all the classes of BP lowering drugs have a similar effect in reducing CAD events and stroke for a given reduction in BP.
### Trials with Angiotensin-Converting Enzyme Inhibitors

- **Aim:** To determine effect of propranolol vs. no propranolol on mortality plus nonfatal MI in pts with prior MI and HFpEF
  - **Inclusion criteria:** Pts ≥62 y with MI and LVEF ≥40% and HF NYHA class II or III treated with diuretics and ACE inhibitors for 2 mo
  - **Intervention:** 79 pts were randomized to treatment with propranolol
  - **Comparator:** 79 pts were randomized to no propranolol.
  - **1° endpoint:** At 32-mo mean follow-up, multivariate Cox regression analysis showed that compared with no propranolol, propranolol reduced mortality 35% (p=0.03) and mortality plus nonfatal MI 37% (p=0.018)
  - **Relevant 2° Endpoint:** At 1-y follow-up, LVEF was increased by propranolol from 57% to 63% (p<0.001) and LV mass was decreased by propranolol from 312 grams to 278 grams (p=0.001) Propranolol was stopped because of adverse effects in 11 of 79 pts (14%)

### Trials with CCBs

- **Aim:** To determine the effect of nebivolol vs. placebo in pts with HFpEF and HFpEF
  - **Inclusion criteria:** Pts ≥70 y history of HF and HFpEF or HFpEF
  - **Intervention/Comparator:** 1,359 pts with a history of HFpEF and 752 pts with a history of HFpEF were randomized to nebivolol or to placebo
  - **1° endpoint:** At 21-mo follow-up, the primary endpoint of all-cause mortality or CV hospitalization was reduced by nebivolol 14% (95% CI: 0.72–1.04) in pts with HFpEF and 19% (95% CI: 0.63, 1.04) in pts with HFpEF
  - **Relevant 2° Endpoint:** HR for reduction of all-cause mortality by nebivolol: 0.84 (95% CI: 0.66–1.08) for HFpEF and 0.91 (95% CI: 0.62–1.33) for HFpEF

### Trials with Irbesartan

- **Aim:** To determine the effect of irbesartan vs. placebo on all-cause mortality or hospitalization for a CV cause in pts with HFpEF
  - **Inclusion criteria:** Pts 60 y and older with HFpEF and NYHA class II, III, or IV HF
  - **Intervention/Comparator:** 4,128 pts were randomized to irbesartan or placebo
  - **1° endpoint:** At 49.5-mo follow-up, the primary outcome of all-cause mortality or hospitalization for CV cause was reduced 5% by irbesartan (p=0.35)
  - **Relevant 2° Endpoint:** Irbesartan did not significantly reduce the secondary outcomes of death from HF or hospitalization for HF, death from any cause and from CV causes, and quality of life

### CANPAP
Arzt et al. 2007 (100)

| **Aim:** Investigate whether suppression of CSA below threshold by CPAP would LVEF & ht tx–free survival. |
| **Inclusion criteria:** |
| - Age 18 to 79 y |
| - NYHA II-IV |
| - HF due to ischemic, hypertensive, or idiopathic DCM |
| - Stabilized w/ optimal medical therapy for ≥1 mo |
| - LVEF <40% |
| - CSA |
| **Exclusion criteria:** |
| - Pregnancy |
| - MI |
| - Unstable angina |
| - Cardiac surgery w/in 3 mo of enrollment |
| - OSA |
| **Intervention:** |
| - CPAP=CSA suppressed, n=57 |
| - CPAP=CSA suppressed, n=43 |
| **Comparator:** |
| Control, n=110: |

### 1° endpoint:
- Transplant free survival - Combined rate of all-cause mortality & ht tx

#### Significant Results

| **1° endpoint:** |
| - Transplant free survival |
| - Significantly different between 3 groups (p=0.016) |
| - Significantly higher in CPAP-suppressed vs. control group (p=0.043) |
| - No difference between CPAP-unsuppressed vs. control group (p=0.26) |

| **2° endpoint:** |
| - AHI |
| - AHI significantly > reduction in both CPAP-suppressed (p<0.001) and CPAP-unsuppressed (p<0.001) groups |
| - AHI significantly > reduction in CPAP-suppressed (p<0.001) and CPAP-unsuppressed (p<0.002) than control groups |

**Mean nocturnal SaO2**
- Mean nocturnal SaO2 significantly > increased in CPAP-suppressed vs. control group (p<0.001)
- No significant difference between CPAP-unsuppressed and control group

### Limitations:
- Post hoc analysis
- Stratification of CPAP-treated pts based on polysomnogram performed 3 mo after randomization.
- Because suppressed and unsuppressed status could not be ascertained until completion of PSG, events that occurred during the first 3 mo could not be included
- The CPAP-CSA–suppressed group was younger, had a lower AHI, and had a slightly lower proportion of central events than the CPAP CSA–unsuppressed group
### CPAP for CSA & HF (CANPAP)

**Bradley et al. 2005 (101) 16282177**

<table>
<thead>
<tr>
<th>Aim:</th>
<th>Test long-term treatment of CSA w/ CPAP in HF pts receiving optimal medical therapy on combined rates of death &amp; ht tx.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Study type:</strong></td>
<td>11 center RCT</td>
</tr>
<tr>
<td><strong>Size:</strong></td>
<td>258</td>
</tr>
</tbody>
</table>

#### Inclusion criteria:
- 18-79 y
- NYHA II-IV
- HF due to ischemia
- HTN, Idiopathic DCM
- Stable condition
- Optimal medical therapy for 1+ mon
- LVEF <40%  
- CSA w/ ≥15 AHI
- >50% of AHI had to be central.

#### Exclusion criteria:
- Pregnancy
- MI
- UA
- Cardiac surgery within prior 3 mon, OSA

#### Intervention:
- CPAP n=128  
- Comparator: No CPAP n=130

#### 1º endpoint:
- Transplant free survival
- No significant difference in transplant free survival between CPAP and control groups (p=0.54)

#### 2º endpoints:
- Hospitalizations: No significant difference between CPAP and control groups (p=0.45)
- EF: Significant increase in EF between CPAP vs. control groups (p=0.02)
- Frequency of apnea and hypopnea episodes
- Significant reduction between CPAP vs. control groups (p=0.001)
- Mean Nocturnal SaO2
- Significant increase between CPAP vs. control groups (p≤0.001)
- 6MWT: Significant increase in 6MWT between CPAP vs. control groups (p=0.016)
- QoL: No significant difference between CPAP and control groups

#### Limitations:
- Underpowered because trial stopped early for low enrollment
Neurohormones: Norepinephrine
• Significant reduction in CPAP vs. control groups (p=0.009)
• Atrial NP: No significant difference between CPAP and control groups

### Ruttanaumpawan et al. 2009 (102) 19189783

**Aim:** To determine whether attenuation of CSA by CPAP in pts w/ HF reduces the frequency of arousals from sleep or improves sleep structure.

**Study type:** RCT

**Size:** 205

**Inclusion criteria:**
- Age 18 - 79 y of age;
- NYHA II -IV
- HF due to ischemic, hypertensive, or idiopathic DCM, stabilized on optimal medical therapy ≥1 mo
- LVEF <40% by radionuclide angiography
- CSA defined as an AHI ≥15, w/ >50% central apneas & hypopneas

**Exclusion criteria:**
- Pregnancy
- MI
- UA
- Cardiac surgery within 3 mo of enrollment
- OSA

**Intervention:**
- CPAP n=97

**Comparator:**
- Control n=108

1º endpoint:
- AHI (central and obstructive)
- Mean and lowest SaO2

**Significant Results**
- in the CPAP group:
  - Central and obstructive AHI decreased significantly over BL and vs. the control group (p<0.001)
  - Mean and lowest SaO2 improved in both the CPAP (p<0.001) and control (p<0.04) but the improvement was significantly better in the CPAP vs. the control group (p<0.001).

2º endpoints:
- No significant improvement in arousals from sleep or sleep structure within or between groups (p=0.14–0.99)

**Limitations:**
- 2º analysis of CANPAP data
- Did not classify arousals as being respiratory or non-respiratory related, and did not examine their timing.

### Kaneko et al. 2003 (103) 12660387

**Aim:** To determine the effect of CPAP on LVEF when awake and daytime BP in pts with HF and OSA

**Study type:** RCT

**Inclusion criteria:**
- HF due to ischemic or nonischemic dilated CM for >6 mo;
- LVEF <45% by radionuclide angiography
- NYHA class II–IV;
- Absence, in last 3 mo, of HF exacerbations while receiving optimal pharmacologic therapy at highest tolerated doses;

**Intervention:**
- CPAP n=12

**Comparator:**
- Control n=12

1º endpoint:
- LVEF when awake
- LVEDD
- LVESD
- Heart rate
- Daytime BP

**Significant Results**
- LVEF when awake

2º endpoint:
- BMI
- Episodes of apnea and hypopnea
- Total
- Obstructive
- Central
- Desaturation index (# hr of sleep)
- Lowest oxyhemoglobin saturation (%)

Obstructive
- Significant reduction in CPAP (p<0.001) but not control group and difference between groups was significant (p<0.001)

- Central
  - No significant difference for CPAP group or between groups

Desaturation index (# hr of sleep)
- Significant reduction in CPAP (p<0.001) but not control group and difference between groups was significant (p=0.008)

Lowest oxyhemoglobin saturation (%)
- Significant increase in CPAP (p=0.004) but not control group and difference between groups was significant (p=0.01)

Total sleep time
- No significant difference for CPAP group or between groups

Stage I and II sleep (% of total sleep time)
- No significant difference for CPAP group or between groups

Stage III and IV sleep (%) sleep (% of total sleep time)
- No significant difference for CPAP group or between groups

REM sleep (% of total sleep time)

was significant (p=0.002)
### Mansfield et al. 2004

**Aim:**
To assess long-term effect of OSA treatment with nocturnal CPAP on systolic heart function, sympathetic activity, BP, and QoL in pts with HF

**Study type:**
RCT

**Size:**
44

**Inclusion criteria:**
- HF due to ischemic or nonischemic dilated CM for >6 mo;
- LVEF <45% by radionuclide angiography
- NYHA class II–IV;
- Absence, in last 3 mo, of HF exacerbations while receiving optimal pharmacologic therapy at highest tolerated doses;
- OSA defined as ≥20 episodes of apnea and hypopnea /h of sleep of which >50% were obstructive

**Exclusion criteria:**
- 1° valvular heart disease;
- Presence of implanted cardiac pacemaker;
- UA;
- MI;
- Cardiac surgery within 3 mo of enrollment

**Intervention:**
CPAP X 3 mo n=19

**Comparator:**
Control n=21

**1° endpoint:**
- **LVEF**
- **Overnight urinary norepinephrine excretion**
- **BP**
- **QoL**

**Significant Results 1° endpoint:**
- **LVEF**
  - Significant improvement in CPAP group (p<0.001) and vs. control group (p=0.04)
- **Overnight urinary norepinephrine excretion**
  - Significant reduction in CPAP group (p<0.05) and vs. control group (p=0.036)
- **BP**
  - No significant difference in CPAP group or between groups
- **QoL**
  - Significant improvements in most domains within CPAP group
  - **SF-36**
    - Significant improvements between groups in 4/8 domains
      - Physical (p=0.03)
      - Vitality (p=0.02)
      - Social (p=0.03)
      - Mental health (p=0.01)

**2° endpoint:**
- Peak Vo2
- NYHA class
- Epworth sleepiness scale
- BMI
- AHI events per h
- Minimum SpO2 saturation

**Limitations:**
- No placebo
- Significant difference between groups in peak Vo2 and mean BP at BL
- Dropout rate = 27%
- Higher than expected death rate
- Higher than expected rate of interventions initiated that may have effected end points
- Small sample size with only 3 females
### Chronic HF questionnaire
- Significant improvements between groups in 3/4 domains
  - Fatigue (p=0.01)
  - Emotional well-being (p=0.02)
  - Disease mastery (p=0.02)

### 2\textsuperscript{nd} endpoint:
**Peak VO\textsubscript{2}**
- No significant difference in CPAP group or between groups

**NYHA class**
- No significant difference CPAP group or between groups

**Epworth sleepiness scale**
- Significant reduction in CPAP vs. control group (p=0.01)

**BMI**
- No significant difference CPAP group or between groups

**AHI events per h**
- Significant reduction in CPAP group (p<0.001) and vs. control group (p<0.001)

**Minimum SpO\textsubscript{2} saturation**
- Significant improvement in CPAP group (p<0.001) and vs. control group (p=0.001)

---

**Date:** Study selected by the chairs in December 2015 and some trials added by the writing committee.

**Death from any cause**

12.5% VAL

12.3% VAL + CAP

**Change in EF:**

Beta-blockers

14,703

Valsartan: 490

SBP >100 mmHg; Cr <2.5 mg/dL

NYHA II-III, IV (only <2% class IV); Mild to severe; EF 27%; BP 123/76; ARF 12%

**NYHA class, QoL scores; Signs and symptoms of HF**

**Significant stenotic valvular heart disease; Active myocarditis; active pericarditis; Planned heart transplantation w/in 6 mo; Coronary angioplasty, CABG, acute MI, stroke, TIA within the previous 12 wk; Diuretics 83%; Beta blocker 55%; Spironolactone 17%; Digoxin 43%**

**Aim of Study**

Aim to find out whether the use of an ARB could reduce mortality and morbidity.

**RCT-parallel, randomized double-blind,**

| Dileuretics 83% Beta blockers 55% ACEI 43% Spironolactone 17% Digoxin 43% |
| 7601 pts (7699 with data) 3803 3796 |
| 18 yrs; NYHA class II-IV; LVEF >40% for at least 4 wk; 3 distinct population: pts with LVEF >40% who were not receiving ACEIs (previous intolerance) or who were currently receiving ACEIs and pts with LVEF >40% |
| SCR > 2.65 mcM/L; serum potassium >5.5 mEq/L; Bilateral renal arterial stenosis; Symptomatic hypotension; Patients with childbearing potential not using adequate contraception; Critical aortic or mitral stenosis; MI, stroke, or open-heart surgery in the previous 4 wk; Use of an ARB in the previous 2 wk |
| NYHA II-IV; Only 3% class IV |
| The primary outcome of the overall program: all-cause mortality; For all the component trials:  CV death or hospital admission for CHF. |
| The annual CV death rate among the placebo group who had reduced LVEF was around 9% and was only 4% in the placebo group of CHARM-Preserved. |
| 3.1 y |
| 66% (23%) pts in candesartan and 945 (25%) in placebo group died (unadjusted HR: 0.91; 95% CI: 0.83-1.00; p=0.055; covariate aHR: 0.93; 95% CI: 0.87-1.00; p=0.093) |
| Fewer CV deaths (691 [18%] vs 769 [20%]; p=0.012; covariate aHR: 0.88; 95% CI: 0.79-0.97; p=0.025) |
| Hospital admissions for CHF (757 [20%] vs 518 [24%]; p=0.0001) |

**CHARM-Overall; 15879886 (T18)**

Compared the effects of high-dose versus low-dose losartan on clinical outcomes in pts with HF.

and to assess its effect in various subgroups defined by ethnic background and demographic criteria — specifically women and members of minority groups.

required, but thereafter its use became discretionary [DIG 94%].

To compare the effects of carvedilol and metoprolol on clinical outcome in pts with HF

To compare the effects of carvedilol and metoprolol on clinical outcome in pts with HF.

Sufficient data do not currently exist to establish the optimum order of initiating chronic HF therapy (ACEI vs. beta blocker). This was the objective of the CIBIS III trial— it compared the effect on mortality and hospitalization of initial monotherapy with either bisoprolol or enalapril for 6 mo, followed by their combination for 6 to 24 mo.

The primary endpoint was time-to-the-first-event of combined all-cause mortality or all-cause hospitalization

In the ITT sample, 178 pt (35.2%) with a primary endpoint in the bisoprolol-1st group, and 186 (36.8%) in the enalapril-1st group (absolute difference -1.6%; 95% CI: -7.6 to 4.4%; HR: 0.94; 95% CI: 0.77–1.16; noninferiority for bisoprolol-first versus enalapril-1st treatment p=0.019)
